The annual rate of mortality in the eight Scotch towns, which had been 19·3 and 18·7 per 1000 in the two preceding weeks, rose again to 18·9 during the week ending Oct. 26th, but was 0·8 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·8 in Edinburgh and 16·9 in Dundee to 20·3 in Glasgow and 21·1 in Paisley. The 545 deaths in these towns included 21 which were referred to diarrhœa, 12 to "fever," 11 to whooping-cough, 10 to scarlet fever, 9 to diphtheria, 2 to measles, and not one to small-pox. In all, 65 deaths resulted from these principal zymotic diseases, against 94 and 91 in the two preceding weeks. These 65 deaths were equal to an annual rate of 2·3 per 1000, which was 0·6 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had declined from 62 to 53 in the three preceding weeks, further fell to 21 last week, of which 6 occurred in Glasgow and 5 in Dundee. The deaths referred to different forms of "fever," which had been 8 and 7 in the two preceding weeks, rose again to 12 last week, and include 9 in Glasgow and 2 in Edinburgh. The 11 fatal cases of whooping-cough were within two of the number in the preceding weeks, and included 5 in Glasgow. The deaths from scarlet fever, which had been 4, 7, and 9 in the three preceding weeks, further rose to 10 last week, of which 6 occurred in Glasgow and 2 in Edinburgh. The fatal cases of diphtheria, which had increased from 2 to 6 in the three preceding weeks, further rose to 9 last week, and included 4 in Edinburgh and 3 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 97 and 92 in the two preceding weeks, rose again to 130 last week, and were 16 above the number in the corresponding week of last year. The causes of 34, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·8 and 24·2 per 1000 in the two preceding weeks, further declined to 20·7 during the week ending Oct. 26th. During the past four weeks of the current quarter the death-rate in the city has averaged 23·3 per 1000, the rate during the same period being 17·1 in London and 17·6 in Edinburgh. The 139 deaths registered in Dublin during the week under notice showed a decline of 23 from the number in the preceding week, and included 15 which were referred to the principal zymotic diseases, against 29 and 20 in the two preceding weeks; of these, 6 resulted from diarrhœa, 5 from "fever" (principally enteric), 2 from whooping-cough, 1 from small-pox, 1 from scarlet fever, and not one either from measles or diphtheria. These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death-rate during the same period being 2·5 in London and 2·7 in Edinburgh. The fatal cases of diarrhœa, which had been 17 and 12 in the two preceding weeks, further declined to 6 last week. The deaths referred to different forms of "fever," which had been 6 and 4 in the two preceding weeks were 5 last week. The mortality from whooping-cough showed an increase, while the mortality from scarlet fever was below that recorded in the preceding week. The 139 deaths in Dublin last week included 18 of infants under one year of age, and 32 of persons aged upwards of sixty years; the deaths of infants showed a further marked decline from those recorded in recent weeks, while those of elderly persons showed a slight increase. Five inquest cases and 6 deaths from violence were registered; and 45, or nearly a third, of the deaths occurred in public institutions. The causes of 9, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL O'FARRELL has arrived in England on transfer to the Home Establishment, and his successor, Brigade-Surgeon-Lieutenant-Colonel Macnamara, has arrived in Cairo. Surgeon-Colonel Maxham has embarked for South Africa in relief of Surgeon-Colonel Hamilton. Surgeon-Captain Macdonald has been transferred to Gosport, Surgeon-Captain Doyle to Cork, and Surgeon-Lieutenant Prynne to Alderney. Surgeon-Captain Maturin has arrived from Gibraltar on completion of a tour of service.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Henry William Alexander Mackinnon, D.S.O., retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following promotions are made in the Bombay Medical Establishment:—Surgeon-Majors to be Surgeon-Lieutenant-Colonels:—J. W. Clarkson and J. Parker. Surgeon-Captain to be Surgeon-Major:—C. J. Sarkies. Surgeon-Captain F. E. Swinton succeeds Brigade-Surgeon-Lieutenant-Colonel Hay as Personal Assistant to the Principal Medical Officer, Bombay Command, the latter officer having vacated the appointment on transfer to the Civil Department. Surgeon-Lieutenant-Colonel F. C. Barker and Surgeon-Captain W. E. Jennings have respectively delivered over and received charge of the Rajkot Prison. Surgeon-

Digitized by Google

Major J. Crimmin, V.C., and Surgeon-Major M. Collie have respectively delivered over and received charge of the Ratnagiri Prison. Surgeon-Captain A. L. H. Dixon, A.M.S., retires from the service, receiving a gratuity.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet-Surgeon R. S. P. Griffiths to the *Alexandra*. Staff-Surgeons: C. A. Macaulay to the *Pembroke*; A. Patterson to the *Endymion*; M. Ronan to the *Warspite*; Herbert Canton to the *Immortalité*; J. L. Lambert to the *Narcissus*; Hugh W. Macnamara to the *Cordelia*. Surgeons: M. L. B. Rodd to the *Grafton* and *Redpole*; F. E. Rock to the *Endymion*; R. T. A. Levinge to the *Vernon*; F. D. Lumley to the *Pigmy*; F. J. A. Dalton to the *Plover*; E. D. Minter to the *Pembroke*; J. C. Durston and P. M. May to the Hong Kong Hospital; H. N. Stephens to the *Centurion* for the *Esk*; W. B. Macleod, M.B., to the *Hearty*; J. H. Pead to the *Alacrity* and for recommissioning; A. E. Kelsey to the *Daphne*; H. Harris and W. Spry to the *Grafton*; E. S. Miller and H. H. Pearce to the *Wildfire*; Cecil H. Rock to the *Vivid*; Thomas W. Phillip to the *Jackal*; Edward S. P. Eames to the *Blenheim*; John M'Ellwell to the *Centurion*; Walter J. Bearblock to Plymouth Hospital. Surgeon and Agent: W. J. Carmichael at Collieston.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Samuel Smith, having resigned his Volunteer appointment, ceases to be an Officer of the Army Medical Reserve of Officers. Surgeon-Lieutenant Francis James Lewis Warwick, M.B., 1st Tower Hamlets Volunteer Rifle Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Lieutenant T. J. Schollick resigns his commission. 1st Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Lieutenant R. J. Hughes resigns his commission. 2nd Volunteer Battalion the Hampshire Regiment: Surgeon-Captain R. T. Cæsar to be Surgeon-Major. 1st Dumbartonshire: Surgeon-Captain T. F. Macdonald, M.B., resigns his commission. 26th Middlesex (Cyclist): Surgeon-Lieutenant R. S. O. Dudfield, M.B., resigns his commission.

THE CHITRAL EXPEDITION AND ENTERIC FEVER.

We learn that, notwithstanding the great care that was taken in regard to the camping grounds and water-supply for the troops on the late expedition, enteric fever broke out in some of the British regiments composing the force. The Commander-in-Chief in India during his recent tour of inspection ordered that samples of the water used by the troops at various camps should be forwarded for chemical and bacteriological examination. We need scarcely point out, however, that it does not at all follow that the samples so forwarded will be identical with the water which was consumed at the time of the outbreak. The conditions may have altogether altered in the meantime; and it is also possible that some of the corps affected in the field may have brought the disease with them from their cantonments. It is alleged in the *Pioneer Mail* of the 3rd ult. that in the wing of the Derbyshire Regiment at Benares all the drinking-water has been boiled since April 1st last, but the results as regards the prevalence of enteric fever have not been at all encouraging. An experiment of this kind is not conclusive, however; although the water may have been boiled for the troops, we cannot be sure that they all drank it or that the boiled water was not subsequently contaminated by being passed through fouled barrack-room filters, to say nothing of the men having consumed impure water in the drinks supplied them in the bazaar. It is a singular fact that enteric fever is one of the scourges of all European armies in the field, and nothing should be left undone to discover and remove, if possible, the causes of this being so. Although we regard contaminated water as one of the most direct and best-established causes of enteric fever, we do not feel at all warranted in saying that it is the exclusive cause. There is still much to be learned about the causation of enteric fever in tropical and subtropical climates, and still more, perhaps, as to the best practicable methods of preventing it on service.

PORTABLE INCINERATORS ON FIELD SERVICE.

It has been suggested that incinerators should in future become a regular part of the camp equipment of Indian campaigns. No doubt incinerators would prove most useful in various ways, especially in sanitation. That is quite obvious but what is not by any means so obvious is the practicability of applying the suggestion. Every ounce of weight to be carried is of importance in a campaign. In every military expedition the great difficulty to be overcome is transport. It amounts to a platitude to say that the multiplication of impedimenta to meet all required needs may become such as to put all rapid movement of a force out of the question, and military success is, after all, the paramount object of warfare. It has also been suggested that portable steam disinfectors should be taken on service, but it seems to us that it might be better and cheaper in the end to burn all infected clothing at once under such circumstances instead of attempting to disinfect it by heat. In favour of incinerators, it may be said that, in addition to their utility in effectually destroying camp refuse of all kinds, they could be employed for this and other purposes. As regards fuel, a proposal of the late Professor de Chaumont, we believe, about the employment of petroleum under certain circumstances might be worth consideration. Our wars in India and elsewhere are seldom on a large scale and commonly in very difficult countries as regards the use of wheeled transport, and are very different in these respects from big Continental wars. At the base of operations and at large temporary camps on the line of communications the supply of incinerators might be practicable; they would certainly be very beneficial in many ways.

AN EXAMPLE WORTHY OF IMITATION.

A wealthy French lady named Furtado-Heine has given her villa at Nice to the Minister of War with a view to its conversion into a "residence of repose" for fifty officers belonging to either land or sea forces. The donation comprises an annuity to cover all expenditure incurred on account of the sick officers as well as the up-keep of the premises and the wages of the *personnel*. What a boon an institution of this description would be to many an officer in our army whose health has broken down in India or elsewhere and whose relations are not rich enough to give him all the comforts necessary for his recovery. It is greatly to be desired that the example afforded by this generous lady may find imitators on this side of the Channel. It would be impossible to devise a more popular and patriotic means for utilising superfluous funds.

DEATHS IN THE SERVICES.

Inspector-General Sir Wm. Mackenzie, K.C.B., C.S.I., at his residence in London on Oct. 29th. He entered the Madras Medical Service in 1835, was Field-Surgeon with Lord Strathnairn in Central India 1857–58, and was appointed Hon. Physician to the Queen in 1857.

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon Surgeon-Lieutenant-Colonel Charles Cormack Greig, 2nd Volunteer Battalion the Gordon Highlanders.

MATRONS' COUNCIL.—At a meeting of the above society, held in the Medical Society's rooms on Oct. 24th, 1895, Mrs. Bedford Fenwick in the chair, a paper was read by Miss Isla Stewart, matron of St. Bartholomew's Hospital, on the subject of a Uniform Curriculum of Training for Nurses. The replies received from matrons and others to a number of questions bearing on the subject were taken up in detail, special attention being directed to the very full expression of opinion from Miss Nightingale. The ease with which ignorant and unsuitable women, of little or no training, obtain work as fully-trained nurses was pointed out, and it was urged that State registration of certificated nurses was the only means of adequately combating this evil. A preliminary course of training and a preliminary examination were advocated, as enabling the authorities to more properly discriminate between candidates and insuring a smaller number of failures during the first year of training, to the great benefit of the hospital patients and the permanent nursing staff. Other questions discussed in the paper were: the manner in which the three years of training should be spent, the establishment of a central board of examiners, the form of certificate to be granted by hospitals, and whether payment or entrance fee should be demanded of the nurses. Discussion on the subject followed, and at the conclusion of the meeting a motion was unanimously carried approving of a uniform curriculum of training for nurses.

"Audi alteram partem."

DUBLIN INFECTIOUS HOSPITALS SCHEME.

To the Editors of THE LANCET.

SIRS,—I have read with deepest interest your leading article upon the attitude of the council of the Dublin Sanitary Association towards the draft scheme, prepared by the superintendent medical officer of health of the city of Dublin, "for the formation of a board for establishing hospitals for infective diseases in the county Dublin."

Although I have the honour to be the President of the Dublin Sanitary Association I do not presume to speak on behalf of the council of that body, which will at the proper time, no doubt, justify the deliberate conclusion at which it has, after due consideration, arrived in regard to Sir Charles A. Cameron's scheme. In my private capacity, however, I desire to make a few remarks upon a topic with the bearings of which I may without presumption claim to be familiar. You say: "The county of Dublin is about to institute an organisation for the isolation of infectious diseases, and the draft scheme has been prepared for submission to Parliament." This, Sirs, is not an accurate statement. The draft scheme has indeed been prepared. It has also been explained to a meeting of representatives of the public bodies concerned, all of whom were very careful to make it perfectly clear that they were present to hear, but not to vote for or against, the scheme. They went to the meeting on Oct. 10th invested with neither power nor authority by the bodies of which they were the delegates. Several of these bodies have since that meeting considered the scheme and repudiated it. The board of guardians of the Rathdown Union have refused to coöperate in any way in the scheme. The Kingstown Township Commissioners have decided to take no further action with reference to it. The Commissioners of the important and wealthy Pembroke township do not approve the scheme and have refused to send representatives to serve on a subcommittee appointed to carry out details. Thus one-half of the "County Dublin" has already declared itself dead against the scheme, which is a "City of Dublin" scheme from beginning to end.

In discussing the first objection urged by the council of the Dublin Sanitary Association you speak of removing "infectious patients from the six or seven general hospitals and similar institutions *in which* such patients are now treated." What do you mean by the words "*in which*"? Surely it is a notorious fact that no general hospital in Dublin receives into its wards infectious patients other than those suffering from typhoid fever. The fever blocks attached to these hospitals are isolated in the grounds surrounding the main buildings. This is the case at the Meath Hospital, Sir Patrick Dun's, the Adelaide, the City of Dublin, and Steevens' Hospitals. Into these fever blocks, further, small-pox has never been received since 1878. As regards other infectious fevers there is, so far as I know, not a scintilla of proof—if you will, it has yet to be proved—that typhus, scarlet fever, or measles has ever spread from the isolated fever wings into the main hospital buildings. In some cases the fever wings are perhaps not all that they should be, but this is a matter of detail. In the face of this explanation you will hardly stand by your answer to the second objection of the council of the Dublin Sanitary Association that the scheme practically deals with one disease only—namely, small-pox. You write: "This argument, however, altogether ignores the fact that other specific infections easily traverse the smaller air spaces comprised *within one and the same institution*, and that the abandonment of the practice of *receiving scarlet fever and similar diseases in the general hospitals* of London and elsewhere has been brought about as the result of the experience that such cases could not *be received into the hospitals in question with safety to the other patients*." No such state of things has existed in Dublin for at least fifteen years. I am glad you frankly admit the force of the third objection of the council to the scheme. It will be bad enough to substitute salaried medical officers for the independent clinical physicians who at present attend fever patients in the epidemic wings of the general hospitals. But it will be nothing short of a disaster to the public, as well as to the profession, if medical students are discouraged from studying fevers by such a change of teachers and by the removal to a distance of their "fever cases." As to the last objection of the council, you say it "is one which carries but little weight." I cannot doubt that this is really your deliberate opinion, but possibly your experience lies among the Anglo-Saxon rather than among the Irish poor. For thirteen years I acted as physician to Cork-street Fever Hospital; for more than twenty years I have been physician to the Meath Hospital; and from this experience I emphatically dissent from your conclusion. The lower orders among an Irish population dread the very name of a fever hospital, and the difficulty of inducing parents to send their sick children to hospital is enormously increased when the order is for a fever hospital and not for the fever wing of a general hospital. I gladly accord my tribute of praise to the present resident medical officers of Cork-street Fever Hospital for the manner in which, by tact and kindness, they have within recent years succeeded in making that institution comparatively popular, but Dr. J. Marshall Day and his colleagues will, if I mistake not, bear me out in what I have stated.

The council of the Dublin Sanitary Association, in the preamble to its objections, distinctly recognised the advisableness of providing adequate and safer accommodation for the treatment of patients suffering from small-pox and other infectious diseases in Dublin and its vicinity, as well as the urgent necessity which exists for the establishment of convalescent homes for patients recovering from such infectious diseases and of refuges for the reception of the inmates of infected houses. But these desirable reforms could all be carried out by a liberal interpretation and enforcement of Sections 149 and 155 of the Public Health (Ireland) Act, 1878, without the necessity of going to Parliament with a revolutionary, cumbrous, unwieldy, unpractical, and unworkable scheme which in one short fortnight has been spurned by half the people who were to work it.

I am, Sirs, your obedient servant,

JOHN WILLIAM MOORE, M.D. Univ. Dubl., F.R.C.P.I.,
Senior Physician to the Meath Hospital, and Consulting Physician to Cork-street Fever Hospital, Dublin.

Fitzwilliam-square-west, Dublin, Oct. 28th, 1895.

*** In answer to Dr. J. W. Moore's question as to the meaning of the words "*in which*," we would say that we regarded "in which" as referring to the treatment of the infectious cases within the precincts of the same institution; and we had regard to the fact that, unless the whole administration of a fever block was entirely distinct from that of other blocks, there was risk of communication of disease from one block to the other. As regards diphtheria, the danger is probably a still greater one; the experience of the Metropolitan Asylums Board as to this is more than suspicious. Our reference to "the smaller air spaces" was governed by similar considerations.—ED. L.

"THE BATTLE OF THE CLUBS."

To the Editors of THE LANCET.

SIRS,—A representative committee of seven medical men practising in Taunton and the surrounding district has been formed to consider what measures can be taken to prevent the increasing abuses connected with club practice. I understand that the medical men at Bridgwater (Somerset) have declined to accept the terms offered by the National Medical Aid Company, which has sent another medical practitioner to the town.

I am, Sirs, yours faithfully,

Shrapnels, Taunton, Oct. 28th, 1895. C. E. ABBOTT.

To the Editors of THE LANCET.

SIRS,—As a small contribution to the history of "the Battle of the Clubs," the following facts may be of some interest to your readers. In a Midland town of about 50,000 inhabitants, chiefly composed of the industrial class, several agents are at the present time employed by a certain insurance company in a thorough canvass of the town. As an inducement to take out policies, these men are offering to provide insurers above fourteen years of age with free medical attendance, and in addition to give the same attendance to all members of the family under this age for

Digitized by Google

a weekly payment of one halfpenny each. Nor is this offer without warrant, because when illness does occur a medical man drives up in a smart victoria, the coachman's hat being decorated with a cockade.

I am, Sirs, yours faithfully,

Oct. 29th, 1895. ADMIRER.

To the Editors of THE LANCET.

SIRS,—At the annual meeting of Convocation of Victoria University, held at Manchester on Wednesday, Dr. John Brown moved a resolution, which, in view of the forcible articles now appearing in your pages under the title "The Battle of the Clubs," will be read with particular interest: "That, in the opinion of Convocation, it is desirable that medical graduates of Victoria University should decline to accept any appointment of any medical aid or similar association in which the conditions of the appointment are such as to degrade the professional man to the position of a paid servant in a trading company." The motion was not proceeded with, but I submit that it is the kind of action taken by Dr. John Brown that is most required if the profession at large is to preserve its self-respect and independence. I am, Sirs, yours faithfully,

Kensington, Oct. 31st, 1895. M.B.

UNQUALIFIED ASSISTANTS AND THEIR PRINCIPALS.

To the Editors of THE LANCET.

SIRS,—In your issue of the 26th inst. I notice that you have drawn the attention of your readers to an inquest held the previous week in the Newington Mortuary (S.E.) on the body of Ellen Preswell, an infant of seven weeks. The mother resided at 77, Pollock-road, Walworth, and was confined of twins early in September. In commenting on this case you state that you have derived *all* your information from the *Daily Telegraph*, and you add further that you shall be glad if there be any incorrectness in your version of the facts to have them corrected by the principal in the case. I gladly avail myself of your kind offer. The report is not correct, because, in the first place, it would make it appear that my assistant attended Mrs. Preswell in her accouchement; and, secondly, that he received a fee *for* so attending.

Such is not the case. I, personally, attended her, and, with the exception of the nurse, no one else, certainly no medical man, was present during her delivery. The mother afterwards made a very good recovery, but of the children I had very slight hopes. It is quite true that my assistant paid a few visits to Mrs. Preswell when she was in the convalescent stage, and on one of these occasions he received *my* fee for attending her. There is nothing wrong about that, I think—nothing, in my opinion, to justify the use of the word "fraud," nor for the insinuation that I allowed my unqualified assistant to do the most important part of my work. Although, from the beginning, I had very little hopes of either of the infants surviving, I refused a certificate on the death of the second child as a protest against what appeared to me to be negligence on the part of those most responsible for seeing it was properly attended to. It is not because the child was of premature birth and delicate that every care should not be taken to preserve its life or prolong its existence. At any rate I did not, under the circumstances, feel justified in giving a certificate, and as my conscience rules my conduct, I am afraid under similar conditions I would again feel obliged to refer the matter to the coroner. My assistant did *not* give a certificate in the case of the child first dead. When she applied for it I was ill in bed, and to save me the trouble he simply filled in the blank spaces and I certified the cause of death. I could, of course, do so in this case, as the interval between birth and death was comparatively short, besides having warned the mother when the child was born that more likely than not she would not be able to rear it. The other I had not seen for some weeks previous to its death. Was I not right to refuse a certificate? I think so.

"Unqualified assistant" seems now to be a term of reproach. Why I know not. Many men that I know of passed creditably every examination but the Final, and previous to its coming off were obliged through death or unexpected reverses of fortune to leave their college and earn their own living. Many of those men to my knowledge led, even as students, exemplary lives; some of them gave evidence of superior intelligence—and are they now, after the years they spent studying medicine, to be precluded from earning their living as assistants? I should hope not. It was misfortune—not their fault—that obliged them to abandon a profession they would have adorned. Such a man was my late assistant. In the notice printed in THE LANCET above the advertisements affecting those gentlemen you state that the General Medical Council do not object to their being employed by practitioners when resident in or near their employers' houses. Permit me to state that my assistants are always under my immediate supervision. We work at the same surgery, and I always take the greatest precaution before accepting the services of unqualified men to warn them that none of the privileges which principals have imposed upon them by the General Medical Council must be ever broken through. Whether those conditions were broken through in this case or not your readers can now see for themselves. I certainly do not think so.

I am, Sirs, yours faithfully,

JAMES J. PHELAN, L.R.C.S. Irel., &c.

84, Rodney-place, New Kent-road, S.E., Oct. 31st.

THE SURGICAL ASPECT OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—In common with many of your readers, I have read Mr. Treves' address in THE LANCET of Oct. 26th with great interest. It is refreshing to read his vigorous comments on the use of that "ghostly relic of the past"—the word "scrofula." So-called "tonics," cod-liver oil, and iodine paint he dismisses with as much contempt as on previous occasions he has dealt with that belated ghost, the linseed poultice. May they all be comfortably buried in the nineteenth century. There is, however, one point in Mr. Treves' paper that I think deserves greater emphasis—viz., the importance of insisting on climatic treatment in the earliest stage of surgical tuberculosis. This principle is readily admitted in theory, but, judging from my own experience, is not always acted upon in actual practice. It is pitiable to see the hopelessly incurable cases that drift down to this district after they have wasted valuable months and even years in trying the effects of "hypophosphites," cod-liver oil, and so-called tonics. The profession and the public have at last recognised the uselessness, if not cruelty, of sending cases of advanced pulmonary tuberculosis to linger and die away from home. Is it too much to ask that surgical tuberculosis should be considered from the same standpoint? I am quite aware that the tubercle bacillus in attacking the lung is attacking a vital organ; at the same time the analogy is sufficiently exact to demand a similar method of treatment. There are dozens of excellent health resorts in England adapted for cases of surgical tuberculosis; in fact, they outnumber by ten to one the resorts suitable for cases of pulmonary disease, because in the treatment of the former a calm and equable temperature is not of such great importance. Much more could be said on this subject, but I do not wish to labour the point. We who live away from crowded cities are able to testify to the sometimes extraordinary effects of plenty of fresh air and sunshine with appropriate surgical treatment. I am glad to see such a distinguished authority as Mr. Treves protesting against over-operating in gland cases. Many glands that I have reluctantly given the benefit of the doubt have disappeared, to my surprise, without the use of the knife, tonics, or even hypophosphites. I know of few problems more difficult to decide than the exact time to operate in some cases of tuberculous glands. I trust that it may not be presumptuous for a provincial practitioner to have called special attention to the importance of the climatic treatment of tuberculosis of bones, joints, and glands at the earliest possible period, and that this variety of the disease should be treated on the same principles as obtain in the treatment of tuberculous phthisis. I am, Sirs, yours faithfully,

Margate, Oct. 29th, 1895. BERTRAM THORNTON.

INFECTIOUS DISEASES IN MAN AND BEAST: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—The subject which I venture to bring before your readers is of such wide scope that I must condense my remarks as much as possible. It is now fully recognised,

Digitized by Google

and every day becoming more apparent, that the infectious diseases of man and the inferior animals are in many cases identical, or at least due to a common cause. Anthrax is common to men and animals, in the former assuming the varied forms of malignant pustule and wool-sorters' disease. Hydrophobia is common to men, dogs, cats, &c. Diphtheria is found in birds and seems to have been transmitted through them to human beings. The relations between scarlatinal disease in the cow and in the human subject are of pressing interest and importance. These are merely examples; I purposely refrain from extending the list to save space. What I wish to urge is that an establishment or establishments should be made in the United Kingdom where the infectious diseases of animals could be practically studied by members of our profession, by veterinary surgeons, and by laymen who were interested in cattle, horses, &c. This may seem to be rather a "mixed" interest; but a moment's reflection will show that it is a "common" interest, since those different classes of men would be furnished with an opportunity of studying subjects which are of intense interest and importance to them all, and the result of such study would be a benefit to mankind and the lower animals. For our profession it would mean a saving of human life and suffering, in the case of veterinary surgeons it would mean success in checking epidemics among horses and cattle, and in the case of agriculturists it would mean a saving of stock and consequently of money. It seems to me that these interests form a very wide and strong basis, and one which should ensure State recognition and support. Of course, as a member of the medical profession, I write in the interests of humanity, but my cause is strengthened by the pleas of benefits to the lower creatures and the saving of money to stockholders. Are there not establishments of this kind on the Continent? Why should we, a rich and practical people, lag behind in such good and necessary measures? If Dr. Thorne Thorne, the worthy medical chief of the Local Government Board of England (who has rendered such valuable services to public health), should see fit to take the matter up it would soon be carried to a successful issue.

I remain, Sirs, your obedient servant,

JAMES W. ALLAN, M.B. Glasg.

India-street, Glasgow, Aug. 5th, 1895.

"THE ADMINISTRATION OF OATHS IN COURTS OF LAW."

To the Editors of THE LANCET.

SIRS,—With respect to your annotation in this week's issue (p. 1058), in which you say you have been unable to discover when the practice of kissing the Testament commenced, I beg to say that in "Haydn's Dictionary of Dates," fifteenth edition, 1876, p. 521, under "Oaths," it is stated: "Oaths were taken on the Gospels so early as 528, and the words 'So help me God and all Saints' concluded an oath until 1550." The authority for this statement is not given, but if substantiated it would show that the *use* of the Gospels (irrespective of kissing the same or not) is of very ancient date. I merely mention this as an interesting point in history. I have always thought kissing the Book most objectionable on all grounds.

I am, Sirs, yours truly,

J. E. BULLOCK, M.D.Brux.

Ladbroke-grove, Notting-hill, London, W., Oct. 28th, 1895.

DEATH RETURNS IN THE STRAITS SETTLEMENTS.

To the Editors of THE LANCET.

SIRS,—In the "Notes from Singapore" in your issue of Aug. 31st there are two mis-statements which I appeal to your sense of fair-play to correct. The first occurs under the heading, "The Government and the Municipality," and is as follows: "The death return for April was delivered by the Government to the municipal authorities so late as June 1st; that this was the first special indication to the medical officer of health that the death-rate in April was so unusually high." The second mis-statement is under the heading, "The Present System of Registration," &c., and is as follows: "In this way this official is kept in total ignorance of the death-rate of the district which is his special care, and he can have no guide or indication which might lead him to suspect the presence of any unusual fatal element until some weeks later." The real fact (entirely omitted by your correspondent) was, and is, that a return of the number of deaths registered by each deputy-registrar within the municipal area was supplied immediately, *every week*, to the municipal health officer. This fact was publicly mentioned by the president in the municipal council,[1] and on July 8th the president of the municipality wrote to the Government: "I have carefully gone over with the municipal health officer the weekly death returns for the months of April, May, and June last, as supplied to him by the registrar-general." It is to be regretted that, owing to the distance between this place and London, your correspondent's report should have had so long a circulation uncorrected.—I am, Sirs, yours faithfully,

MAX. F. SIMON, M.D.,
Principal Civil Medical Officer and Registrar-General of Births and Deaths, Straits Settlements.

Singapore, Oct. 1st, 1895.

*** We have received a communication to the same effect from Dr. W. R. C. Middleton, medical officer of health for Singapore. We regret to have been misinformed by our correspondent.—ED. L.

ANNUAL MEETING AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to call the attention of Members of the Royal College of Surgeons of England to the fact that the annual meeting of Fellows and Members takes place on Thursday, Nov. 7th, at 3 o'clock P.M. precisely, at the College, Lincoln's-inn-fields? Members are urgently requested to attend on that day and give their support to important resolutions affecting the welfare of the Members and the government of the College which will be submitted to the meeting by the Society of Members of the College.

I am, Sirs, yours obediently,

JOSEPH SMITH,
President of the Society of Members of the Royal College of Surgeons of England.

THE THERAPEUTIC VALUE OF INTESTINAL ASEPSIS.

To the Editors of THE LANCET.

SIRS,—I was much interested in reading in THE LANCET of Oct 26th the remarks of Dr. Williams on the treatment of typhoid fever by the antiseptic method of using chlorine. I wish only to say that as far back as 1857, during my apprenticeship in Yorkshire, we used this treatment for a severe epidemic of scarlet fever, and since that time I have always used chlorine in the treatment of enteric fever with the very best results; so that this way of prescribing can hardly be attributed in the first place to Dr. Yeo.

I am, Sirs, yours truly,

Harrow-road, Oct. 29th, 1895. A. L. GRIFFITH.

THE VALUE OF COD-LIVER OIL.

To the Editors of THE LANCET.

SIRS,—On reading Mr. Treves' learned discourse on the Surgical Aspect of Tuberculosis, published in THE LANCET of Oct. 26th, I was much struck with the following paragraph on the treatment of this disease. "Tuberculous subjects, especially children, appear to be benefited by taking an extra amount of fatty matter in their food during the cold weather. This can be supplied in the form of fat, butter, or cream. There is no excuse, so far as I am aware, for the administration of cod-liver oil. In all probability there is no more nauseous form of fat to be found, and I am not aware that it contains any chemical quality other than that of oil. ..... If adults like this oil by all means let them take it; but it is unkind to force it upon children," &c. Now, in view of the fact that practically every surgeon orders cod-liver oil in this and other diseases, and also that children so thoroughly dislike it, I think that you would be doing the profession and public a kindness if you allowed the active and special advantages of this fat above ordinary fats

[1] See Straits Times of July 4th.

Digitized by Google

and butter (for not many patients can get cream) to be discussed in your columns. Personally I have seen children who were taking the ordinary diet suitable to them, including butter and dripping, &c., improve markedly when ordered this oil as a medicine, and I have no doubt many other medical men have seen the same thing.

I am, Sirs, yours truly,

Oct. 28th, 1895. E. H. W.

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1071.*)

DISUNION IN THE PROFESSION AND SLATE CLUBS AT GREAT GRIMSBY.

EVERY one of the towns so far visited in the course of this inquiry possesses a medical society. An effort to group and organise the medical profession has been made. The union may not be so complete or so far-reaching in its purpose as is desirable, still some sort of organisation exists. It seemed, therefore, that it was time to visit a town where there is absolutely no organisation and where the medical profession has never sought to act in union. For this purpose I selected Great Grimsby. It is a new town which has grown with the railways that rendered the inland fish trade possible. At the same time it is a town that has a population composed almost exclusively of fishermen, workmen, and business men. Under such circumstances the population is not likely to very generally appreciate the sacrifices necessary to acquire the training and education by which alone a practitioner can obtain his qualifications. The tendency is to estimate the value of a medical man's work by what he actually does in the presence of the patient, and by the medicine he gives him, and no allowance is made for his previous expensive studies. Thus it often happens that patients refuse to pay fees unless a bottle of medicine is given them. They do not think much of the advice the medical man offers; but a bottle of medicine is something substantial, and they realise that it would not be honourable to take it without payment. They can go to a shop and talk to the shopman without paying, but they must pay if they take any of his goods away, and they look upon the medical man in the same light. They will take his advice gratuitously, but think themselves bound to pay for the medicine. Under these circumstances 2*s*. 6*d*., including a bottle of medicine, is considered a somewhat high price. Medicine can be had much cheaper from a druggist. It is, therefore, difficult to explain to so unappreciative a people that the pay given to club medical men is inadequate. They not infrequently answer that they think the pay is very good and would be glad to do the same work for the same price, thus showing how completely ignorant they are of what the work is in itself and what previous study and labour are required. From people of this sort there is little or no hope of obtaining good fees. Grimsby is a town where there is plenty of work to be done, but for very small fees. It is not a town that offers any particular inducements to medical men, and in comparison with the number of the population there are not many practitioners established there. Those who have settled in the town have not shown any particular disposition to come together and work together. In the district of New Clee, which has been recently added to the borough of Grimsby, the principal local practitioners have met. They have formed no society, but they have spoken of their common interests and have agreed in an unofficial manner to help each other and to work together. This sort of friendly understanding does not constitute a union. The profession at Grimsby are therefore still disunited. Nor does there seem to be any hope for the present that a union will be constituted. This, I was assured, could only be done if some outside agency or person were to take the matter in hand. No local practitioner holds so pre-eminent a position and exercises a sufficient personal influence to take the initiative. The competition between the practitioners is so keen that, if any one of them took any decided steps with a view to form a medical union, his motive might be misinterpreted. It is with regard to such towns as Grimsby that a great national union could render efficient service. An appeal from some outside and respected authority should be made to the practitioners of the town, calling upon them to form themselves into a union, and this would probably meet with a favourable response.

It is needless to say that, with so large a working-class population, there are many benefit societies at Grimsby; but the speciality of this town seems to consist of slate clubs organised by public-house keepers. There is much to be said in favour of the purpose for which friendly societies were originally constituted, but this scarcely holds good with regard to public-house slate clubs. To secure medical aid for people who are really too poor to pay the usual fee is a very good object, and the grievance against friendly societies is that they have departed from their original aim. But the public-house keeper has hit upon this very ingenious device for keeping his customers together, and proposes to take upon himself the trouble of organising for their benefit a slate club. The general terms are the payment of 6*d*. per week, the publican acting as cashier. Out of this sum of 26*s*. per annum there is paid to the medical officer of the slate club 2*s*. 6*d*. for each member and for each year. The disposal of the remainder of the money varies a little in different clubs. As a rule, a financial allowance is made to those members who fall ill during the course of the year. The great attraction, however, of the slate club is the fact that it is a yearly club. At Christmas all the money that remains in hand is equally divided among all the members. If there has not been much illness, there is a goodly sum to share among those members who have been regular in their payments; so that it sometimes happens that the members have returned to them at Christmas 10*s*., sometimes 15*s*. or more, out of the 26*s*. they have paid in 6*d*. weekly instalments. This sum, coming at Christmas, is extremely useful. Then there is another great advantage. The publican does all the work; he organises and manages everything, and no one has the slightest fear that he will tamper with the money entrusted to his care. There is no bother about electing committees, secretaries, and treasurers, or obtaining registration under the Friendly Societies Act. The member of the slate club is spared all these anxieties and troubles, and he has to pay no fees for management: every penny he gives he gets back again either in cash or in kind. In one sense nothing could be more advantageous to the members—i.e., if one assumes that the members are all regular frequenters of public-houses. It is also easy to understand that it is in the publican's interest to take upon himself the trouble of organising a slate club which helps to keep his customers round his bar. They go there at least once a week to pay their subscriptions, and when at Christmas they receive their share of the balance remaining in hand a good portion of it may be spent over his counter.

If slate clubs afford considerable advantages to the members and the publicans who organise them the same cannot be said with regard to the medical officers engaged in this service. First of all, the allowance is only 2*s*. 6*d*. per member. Nevertheless, one medical practitioner assured me that he made a very good income from slate clubs. He pointed out that a great many of the members were fishermen, and when they required medical attendance they might be away fishing in some distant part. Some of them also belonged to friendly societies and were not certain to call for the slate club medical man. Then the slate clubs were in the main composed of men in the prime of life, so that, in the natural course of events, they would not require much medical care. Therefore, though the sum of 2*s*. 6*d*. was very small, there was not much work to be done. Also, as the members of the slate clubs were anxious to have as large a balance as possible remaining to be shared amongst them at Christmas, they took good care to keep out of their clubs unhealthy members.

Another practitioner whom I questioned on the subject did not take such a favourable view of this institution. He pointed out that it was to the interest of the publican to make hard drinkers members of his club, and this meant a great deal of work for the medical attendant. On the other hand, the publican must be careful to exclude men who were constantly ill, as this would prevent the benefits and thus disappoint the other members. Yet, again, it was objected that when one slate club got rid of a bad member he soon managed to gain entrance into some other slate club. However this may be, there is one point on which no doubt whatsoever can be entertained—namely, that there can be no such thing as a wage limit. If there was a wage limit it would be the other way about; for, instead of

Digitized by Google

seeking to prevent persons with good incomes from joining the club, the publican would find it suit his purpose best to keep the poor away. Thus it is that smack-owners, skippers of fishing boats, and others who make good yearly incomes are members of slate clubs, and by means of these institutions only pay 2*s.* 6*d.* a year for their medical attendance. The difficulty with regard to a wage limit, therefore, applies especially to the slate club; but this institution will be viewed with far greater apprehension by those who are more solicitous of the dignity than of the material interests of the profession. It is bad enough that medical men should be utilised as a sort of bait to enable touting agents to secure the payment of premiums for life insurances; still, if people are persuaded to insure their lives because medical insurance is thrown in as an extra inducement, there is nothing injurious, wrong, or immoral in the insurance of a life. But by becoming the medical officer of a slate club the practitioner practically lends his skill and science to promoting the interests of the publican.

Under these circumstances I was not surprised when one of the practitioners on whom I called explained that members of clubs entitled to the attendance of the medical officers of the clubs often only consulted them for slight ailments and, when anything serious occurred, called in a private practitioner and paid the usual fee. Another medical man told me that he was treating an entire family except the father, who was attended by his club medical attendant because, having to pay for his family, this man preferred that they should have someone other than his club medical officer. On the other hand, it must be recognised that some club officers lead a terribly hard life in this town. Seamen arrive with a large accumulation of wages in their pockets; this they spend in riotous living, and so rapidly that it would seem as if their sole object was to get rid of the money as soon as possible. Perhaps they have an instinctive feeling that the more quickly it is spent the less mischief will be done. Nevertheless, there is time enough for much disease to result. Practice among such a population is not pleasant, and at Grimsby there are very few better-class patients to relieve the monotony of attending either very poor people or a rough, though fairly well-paid, seafaring population.

Grimsby, Oct. 24th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The School of Medicine.

IT is becoming gradually more and more difficult for any former student of the Liverpool Royal Infirmary School of Medicine to recognise his old school in the buildings of the Medical Faculty of the Liverpool University College. Formerly there was the second Royal Infirmary, a building defective from the very first in consequence of the architect having forgotten the stairs in his original plan, and in being a huge rambling pile of buildings. The School of Medicine was located in a small building the capacity of which was severely tested in 1860 by the rush of students who entered to escape the preliminary examinations. There was also the Lunatic Asylum and the Lock Hospital. Of all these buildings the last named is the only one which remains *in statu quo*. The third Royal Infirmary is as free from defects as its predecessor was full of them, being even in these days of almost daily improvements a model hospital. Of the old school building little remains, and before long it will in all probability have been entirely rebuilt. The buildings of the Liverpool University College occupy a considerable part of the adjoining space, which will soon be entirely covered with them. When these are completed the facilities for teaching chemistry and physiology will be equal to those of any medical school.

The Anatomical Rooms.

These continue to receive additions and improvements, and at the present time students possess ample facilities for the practical study of anatomy. Before long new buildings, which will add greatly to the comfort and convenience of Professor Paterson, his assistants, and the students, will be complete, while later it is hoped that greater accommodation for an increased number of students may be obtained.

Hospital Practice.

The proximity of the Royal Infirmary to the college induces the larger proportion of students to attend its practice. But the practice of the Royal Southern Hospital is recognised by all the examining bodies, and a certain proportion of students attend it. Before long there will be a new Northern Hospital on the site of the existing hospital, but with a greatly increased area, and efforts will be made by its medical staff to ensure the erection of a hospital which shall be in all respects worthy of "Greater Liverpool." The present hospital has for a long time past been wholly unequal to the demands made upon it.

Penetrating Wound of the Abdomen and of the Intestines.

Referring to the case of the woman admitted into the Northern Hospital under Mr. Puzey's care a fortnight ago, and given in detail in my last letter,[1] it is very satisfactory to state that she is still living and that there are hopes of her recovery. The injury was alleged to have been caused by her husband, who is not yet in custody. The case is of great interest both surgically and in its medico-legal aspect. It is certainly a triumph of surgery to change what might have been a charge of murder into one of wounding.

Oct. 29th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Court.

AT a meeting of the Edinburgh University Court held last week various matters of medical interest were decided upon. The recognition of the two Edinburgh Schools of Medicine for Women was continued for another year under the original conditions. It was also agreed that the pathological gallery in the Museum should be open one day a week to women students in medicine. The Court also admitted women to the advanced courses in botany and natural history for purposes of graduation in science and to the class of physics for purposes of graduation in medicine. Professor Selby of University College, Cardiff, was recognised as a teacher whose course in physics should qualify for graduation in medicine, and the University of Sydney was recognised as a medical school, the classes at which should qualify for graduation in medicine at Edinburgh both for men and women.

General Council of the Edinburgh University.

The statutory half-yearly meeting of this body was held last week in Edinburgh, Sir W. Muir presiding. Dr. Heron Watson was reappointed an assessor in the University Court, and Dr. Joseph Bell was appointed, in succession to Dr. John Duncan who had intimated that he did not desire re-election. The report of the finance committee indicated that under the new arrangements the University exchequer was running dry, and it was suggested that a combined appeal should be made to the public for funds. This, however, was objected to as the time was not opportune for such an appeal and also in view of the diminution in the number of students.

St. Andrews Ambulance Association.

The annual meeting of the subscribers to this useful association was held last week. It appeared that during the past twelve years 9942 men and women had been trained in ambulance work. The association had also instituted a waggon service and had distributed letters through the town. The balance-sheet showed a balance of £116.

Opening of the Royal Medical Society, Edinburgh.

This society was to have been opened last week by an address from Dr. Clouston. This arrangement, unfortunately, had to be abandoned owing to the illness of Dr. Clouston.

Sir James Crichton Browne at Hawick.

Sir James Crichton Browne lectured last week at Hawick on Brain Rest.

The Pharmaceutical Society's Proceedings.

In the Dundee Sheriff's Court a grocer's assistant was last week charged under the Pharmacy Act with selling opium, which at the time formed an ingredient in a quantity of Powell's balsam of aniseed. A plea of guilty was tendered.

[1] THE LANCET, Oct. 19th, 1895.

Digitized by Google

The sheriff appears not to have sympathised with the prosecution, for he stated that if the sale of a substance, a mere ingredient of which was poison, was actionable it was sufficient for the prosecution of every publican and grocer in the city. He, however, after some differences with the counsel for the prosecution, accepted the plea, but said that if a case of the same kind was brought before him again it would require to be proved that the quantity of poison sold was likely to cause injury to health. The purpose of the Act was to protect the community and not to constitute a monopoly to any pharmaceutical or other society. The agent for the society stated that the Privy Council had compelled them to take proceedings. A fine of 1*s.* with expenses of £1 1*s.* was inflicted.

The Quatercentenary Celebration at Aberdeen.

The quatercentenary celebrations at Aberdeen University were duly carried out on Oct. 24th and 25th, but in consequence of the lamented death of Mr. Charles Mitchell, LL.D., which occurred last August, they were on a much less extensive scale than was originally contemplated. Mr. Mitchell's generous munificence has, among other advantages, enabled the University to erect a Graduation Hall and Students' Union, and to heighten and ornament the tower of the Marischal College. A clock and bell were also placed in the tower, and on Oct. 24th the clock was set in motion by Miss Mitchell, a daughter of the deceased donor, in presence of a very large assembly of members of the University and the general public. The handsome rooms composing the Students' Union were then formally opened, and the remainder of the day was filled up by divine service in King's College Chapel and social festivities. On Oct. 25th the Marquis of Huntly, who is the Lord Rector of the University, opened the new Mitchell Graduation Hall, and honorary degrees were conferred on a number of prominent individuals. In the afternoon the Lord Rector addressed a large audience his subject being entitled "Historical Interest," and the celebrations were brought to a close by a dinner and a torchlight procession in the evening.

Oct. 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dinner to Sir Christopher Nixon.

A COMPLIMENTARY dinner was given to Sir Christopher Nixon on Thursday, Oct. 24th, on the occasion of his receiving the honour of Knighthood. The assemblage at the Shelbourne Hotel included many members of the medical as well as of the clerical and other learned professions. The chair was occupied by the Right Reverend Monsignor Molloy; and among the company were the Most Reverend Dr. McCormack (the Roman Catholic Bishop of Galway), the Lord Mayor of Dublin, Sir John Banks, K.C.B., and Mr. Henry Thynne, C.B.

The Banbridge Union.

A special meeting of the Banbridge board of guardians has been held with reference to a statement by Dr. Moorhead, honorary secretary of the Workhouse Medical Officers' Association, read before a meeting of the council of the Irish Medical Association, in which the Banbridge Union was put in the lowest class—those in which proper sanitary appliances, efficient nursing, and suitable furniture are absent—and that the guardians had declined to make any improvement. In reply to such a charge a guardian pointed out that the sanitary scheme was prepared by an eminent London engineer, that there are constantly three trained nurses, with others in case of emergency, and that the infirmary beds had woven wire and hair mattresses; the dietary also was second to none in such places in Ulster. Dr. Hawthorne, medical officer, said there was no foundation for Dr. Moorhead's statement, so far as the Banbridge Union was concerned. It was then resolved unanimously that, having considered Dr. Moorhead's statement and heard Dr. Hawthorne's report, the board considered the aforesaid statement to be unfounded, and that it should be publicly contradicted.

Burning Accidents in Belfast.

At an inquest on Oct. 22nd on a fatal case of burning in a child aged five years attention was drawn to the number of such cases in Belfast. It was the sixth inquest of the kind held by the coroner in October, and during the twelve months ending Aug. 31st 232 persons had been treated for burns in the Royal Hospital, and of that number thirty-two had succumbed to their injuries. In a large number of cases of this nature the victims are children who through the carelessness of their mothers are left alone.

The New County Monaghan Infirmary.

The old infirmary building, which was disposed of for £1000, has passed into the possession of the governors of the county Monaghan Asylum, and at present is used as an auxiliary house for the treatment of lunatics; while the old gaol at Monaghan is being converted into a new infirmary. At present the governor's house at the gaol is being used as a temporary infirmary. The work of alteration and reconstruction of the gaol into an infirmary will probably not be completed until spring.

The Outbreak of Fever at Ardboe, County Tyrone.

At the weekly meeting of the Cookstown guardians, held on Oct. 26th, Dr. Clibborn, Local Government Board inspector, reported he had gone over the infected district with Dr. Burgess, and referred in the highest terms to the way in which Dr. Burgess and the relieving officer had discharged their duty under circumstances of great difficulty. Dr. Clibborn suggested that the sanitary authority might make use of the provisions of the Labourers Act with a view to the gradual improvement of the dwellings of the labouring classes, especially in the infected districts, where the people live partly by fishing and partly by agricultural labour. It is probable that want of cubic space in the houses where these people live, combined with overcrowding and filth, has had to do with this outbreak of typhus fever.

The Battle of the Clubs at Cork.

It will be in the recollection of your readers that a Mr. Carroll took proceedings in the Cork Police-court for the recovery of sick pay from his club, a branch of the Irish Foresters. The magistrates gave him a decree for the full amount, but the case came on again on appeal recently before the Recorder. Counsel were engaged in the case. It was admitted that a very hostile feeling existed against Mr. Carroll because he had thought fit to call in the assistance of a medical man unconnected with the club. The counsel representing the appellants directed his attention principally towards endeavouring to extract from the Recorder an opinion hostile to the action of the Cork profession in opposing the encroachments of the clubs, but the Recorder, who has the reputation of being a very sound lawyer, simply confined his attention to the case before him and avoided all extrinsic subjects. It was stated that the committee of the club felt annoyed because they have "an uphill fight," and they considered Mr. Carroll had deserted them by not continuing under the care of the club medical officer. Dr. O. T. O'Sullivan, under whose care Mr. Carroll now is, stated in evidence that the unfortunate man has a cavity in one of his lungs. The Recorder animadverted very strongly on the action of the committee in refusing sick pay to such a patient, and confirmed the decision of the court below, with 40*s.* costs. It is to be hoped this will prove a salutary lesson for the Cork clubs in more ways than one.

The Cork District Lunatic Asylum.

At a meeting of the board of governors held recently there was a protracted discussion with reference to the necessity of providing increased accommodation owing to the various boards of guardians objecting to be responsible for the charge of harmless lunatics. The expenditure likely to be involved is naturally causing much anxiety to the governors. One speaker suggested that a new building would cost £200,000, and added that if the present "wave of lunacy" should subside a more or less useless tax would have been put on the ratepayers, and he accordingly suggested that one of the existing workhouses should be fitted up as an auxiliary asylum. Another governor stated that at the end of last year there were 2021 inmates in the asylum, that there are 500 lunatics in the workhouses of the county, and 400 idiots at large, and he said that if the 500 lunatics in the workhouses, with perhaps the whole of the 400 idiots, were sent to them, their establishment would become unmanageable, at least from a medical point of view. Eventually a resolution was adopted to the effect that the increased accommodation should be provided within the present asylum grounds.

The Queen's College, Cork.

Dr. McArdle, who had been a student of the Queen's College, Cork, had the distinction of being the first out of

all Ireland at the recent Royal University examinations for the degrees of M.B., B.Ch., and he is now Demonstrator of Anatomy in his *alma mater*.

Relative Consumption of Alcohol in England, Ireland, and Scotland.

A recent return shows that during the year 1894 the cost of drink consumed per head in England, Scotland, and Ireland was respectively £3 17*s.* 4*d.*, £3 1*s.*, and £2 2*s.* 8*d.* One of the Cork papers, commenting on the subject, says: "A significant fact about the figures is that they prove Ireland to be twice as sober a country as England and once and a half as sober as Scotland."

Oct. 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sero-therapy as a Prophylactic of Tetanus.

AN instructive paper on the above subject was read at the Académie de Médecine on Oct. 15th by M. Nocard of the Veterinary School of Alfort. He began his remarks by reminding his audience that, whilst being extremely sensitive to the influence of heat, the toxine of tetanus shared with that of diphtheria the property of filtering virtually intact through porcelain. It is possible to procure some specimens of tetanus toxine capable of killing the guinea-pig at the dose of $\frac{1}{5000}$th of a cubic centimetre; and M. Nocard has succeeded in killing strong horses with an injection of only $\frac{1}{10}$ c.c. or two drops of this same toxine. Animals subject to tetanus can, however, be rendered refractory to these poisons by the inoculation of minute doses of the pure toxine or of the toxine previously heated to 65° or 70°C., or again of the toxine mixed with weak Gram's solution. The inoculations should be frequently repeated at more or less short intervals and the dose injected gradually increased. MM. Roux and Vaillard, as also M. Nocard himself, have thus succeeded in immunising certain horses who subsequently remain indifferent to a massive injection in the jugular vein of 250 to 300 c.c. of tetanus toxine—a quantity sufficient to kill 2500 uninoculated horses. The serum of these immunised animals is, moreover, endowed with prophylactic properties. This anti-tetanic serum sometimes possesses quite remarkable powers; a certain horse "vaccinated" by M. Nocard supplies a serum so active that an injection of so small a quantity as the ten-thousandth part of the body weight of a guinea-pig guarantees that animal from the effects of a dose of toxine invariably mortal to the same animal unvaccinated. But the immunity of "vaccinated" animals, although acquired immediately after the injection, is short-lived, lasting only four, five or six weeks, and being in this respect distinctly inferior to "vaccination" with attenuated microbes. A conclusive experiment to prove the uselessness of "vaccination" with anti-tetanic serum even when combined with amputation of the inoculated part was then conducted by M. Nocard. Three long-tailed sheep each received in the tail extremity a splinter impregnated with dried tetanus spores. At the first sign of tetanus the tails of two of the sheep were amputated at a point twenty centimetres above the seat of infection. One of these tail-amputated animals then received a dose of serum adequate for the protection of the normal animal, these injections being repeated every two hours. All three sheep succumbed without any difference being discernible in the symptoms. But the prophylaxis of tetanus opens up a more hopeful field. In certain districts of France tetanus is extremely common amongst horses the subjects of operations or accidents, such as castration, bites of insects, a nail-wounded hoof, tail-docking, wounds of limbs, &c. Since December, 1894, M. Nocard has supplied to veterinary surgeons anti-tetanic serum, recommending the injection of 10 c.c. behind the shoulder immediately after the receipt of a wound, operative or accidental, liable to be followed by the disease, the "vaccination" to be repeated twelve or fourteen days later. This treatment was applied to 375 animals, 327 being horses, mules, or donkeys, 47 lambs, and 1 an ox. Each received two injections at a fortnight's interval of 10 c.c. each for the large and 5 c.c. for the small beasts (sheep). In each instance the injections proved inoffensive. All the animals belonged to stables or farms where tetanus had made victims some days, weeks, or months previously; several of them had as neighbours tetanic animals, and some had been wounded at the same time and in the same manner as non-treated companions who became tetanic. Not one of these "vaccinated" animals died. M. Picard, veterinary surgeon of Sourdou, lost from tetanus in four years fifteen horses after castration or tail-docking. In 1895 not one of his operated horses has had the disease, thanks to preventive "vaccinations" in infected localities. Again, M. Coret of Aubervilliers has met with thirty or forty cases annually of tetanus in horses during the last fifteen years. During the first half of the present year he has treated fifty-four wounded horses with the serum, the lesions all enjoying an unenviable reputation for tetanic complications. Not one horse contracted the disease. During the same six months the same practitioner saw seven horses with tetanus untreated with serum. Finally, M. Nocard received a telegram on May 21st, 1895, from M. Gellez, veterinary surgeon of Carvin, asking for serum for forty-nine recently castrated lambs. Nine had already succumbed to tetanus; on May 23rd a first injection of 5 c.c. was given to the forty survivors. Two of these died on the same day, whilst the thirty-eight recovered. The castration had been practised by the shepherd on May 2nd by the ligature (of the cord) method.

Paris Hospital Statistics.

I gather from official sources that the average numbers of patients present at one given time in the Paris hospitals are as follows: General hospitals, 7900; special hospitals, 2000; children's hospitals, 1900; and Maison Dubois (paying hospital), 149. The average annual admissions are: General hospitals, 115,000; special hospitals, 32,400; children's hospitals, 13,800; and Maison Dubois, 2290. The deaths in hospital were in 1892 (the latest mortality figures refer to this year, 1892) 16,682, 12,107 occurring in the general, 1254 in the special, 2825 in the children's, 159 in the temporary, and 537 in the paying (Dubois) hospitals. The number of days spent in hospital in 1892 were: General hospitals, 3,562,113 (women, 1,238,708; children, 318,752); special hospitals, 867,034; children's hospitals, 891,766; Maison Dubois, 96,270; and temporary hospitals, 153,819. The average annual number of deaths for the whole of Paris being 55,000, it will be seen that, adding to the figure 16,682 quoted above the 1800 occurring in *hospices*, a large proportion—about one-third—take place in charitable institutions. The strain on hospital accommodation is so great that of 69,899 applications for admission made at the Bureau Central in 1893, there were 38,689 refusals due to want of beds. The work done by the Paris medical confraternity may be judged of by the following supplementary figures: Patients treated gratis at home, 112,608; of these 33,336 were paupers and 79,122 only in straitened circumstances. This number (112,608) yielded 4057 deaths. There were 15,207 women attended gratis in their confinements at home.

The New Director of the Pasteur Institute.

The new director, Émile Duclaux, was born at Aurillac in 1840, entered the École Normale Supérieure in 1859, was admitted Agrégé des Sciences Physiques in 1862, from which year until 1865 he was Prèparateur to M. Pasteur. Docteur-ès-Sciences in 1862, he has been successively Professor at the Lycée of Tours (1865–66), Professor of Chemistry at the Faculté des Sciences of Clermont (1866–73), and Professor of Physics at the Faculty of Sciences of Lyons (1873–78). Returning to Paris as Professor of Physics and Meteorology at the Institut Agronomique, he was appointed the same year (1878) Lecturer at the Faculty of Sciences of Paris, where he has been since 1888 Professor of Biological Chemistry. A long association with M. Pasteur marked him out as the fittest person for the post of sub-director, a position he has now left for the directorship. In 1894 M. Duclaux was elected a Member of the Academy of Medicine and of the Academy of Sciences. He is, besides, an *officier de la Légion d'Honneur*. M. Duclaux is Director of the "Annales de l'Institut Pasteur," each number of which contains a contribution from himself. His published works include the following:—"Études relatives à l'Absorption de l'Ammoniaque et à la Production d'Acides gras volatils pendant la Fermentation Alcoolique" (Thèse de Doctorat-ès-Sciences, 1862); "Sur la Fermentation Alcoolique" (Comptes rendus de l'Académie des Sciences, 1863; ibid., 1864); "Sur un nouveau Procédé pour l'Étude et le Dosage de l'Alcool du Vin" ("Annales de Chirurgie et de Physiologie," 1874);

Digitized by Google

"Sur la Matière colorante du Vin" (ibid., 1874); "Sur les Acides Volatils du Vin" (ibid., 1875); "Ferments et Maladies" (1882); "Premier Mémoire sur le Lait" ("Annales de l'Institut Agronomique," 1882); second memoir (ibid., 1883) on "Les Phosphates du Lait" (1894); "Sur le Rôle Protecteur des Microbes dans la Crème et les Fromages" (1894); and "Le Lait" (Études Chimiques et Microbiologiques, 1894). M. Duclaux is also the author of several memoirs on "La Sériciculture" in the "Annales de l'École Normale" and the Comptes rendus de l'Académie des Sciences (1869-78); and of sundry studies on "Le Phylloxéra" (*même recueil*, 1872-75). Dr. Roux, the new subdirector, whose name will be familiar to your readers in connexion with the new treatment of diphtheria, was born at Confolens in 1853. Beginning his medical studies at Clermont, where he worked in M. Duclaux's laboratory, he came to Paris, where he became Aide de Clinique at the Faculty of Medicine; Préparateur to M. Duclaux at the Sorbonne; and then Préparateur to M. Pasteur, whom he followed from the Rue d'Ulm to the Rue Dutot in the capacity of Chef de Service.

Oct. 29th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Bardeleben's Successor.

PROFESSOR König of Göttingen, who has been elected by the faculty of Berlin University as successor to the late Professor Bardeleben is reported to have consented to his nomination, and will within a few weeks undertake the two conjoint offices of Ordinary Professor of Surgery and chief surgeon of the Charité Hospital. He might have been appointed to this chair in 1882 in succession to the late Professor von Langenbeck, but as he then declined to leave Göttingen for Berlin Professor Bergmann was elected. Professor König is one of the most renowned surgeons of Germany and is very well known in Berlin as one of the most regular attendants at the annual surgical congresses and as taking an active part in the discussions. The weight of his authority has more than once been beneficially employed in restraining the undue enthusiasm of younger men for new methods and remedies, and although his opinions in this respect have sometimes been regarded as old-fashioned it has nearly always been the case that time has proved the soundness of his judgment. His treatise on Surgery is now the best German book on the subject, Bardeleben's work not having been re-issued of late years. He is also the author of a great many articles and memoirs relating chiefly to diseases of the joints. Being an excellent operator and a very able teacher, he is certain to be heartily welcomed by the medical profession and the students of this city.

Professor Virchow's Eulogy of M. Pasteur.

The Berlin Medical Society resumed its meetings on Oct. 16th, and the renewal of the professional gatherings, together with the opening of the University lectures, has now put an end to the dull season in Berlin medical life. At the first meeting Professor Virchow, the President, read an address commemorating the deceased members, and giving special prominence to the late M. Pasteur of Paris, who since 1892 had been one of the few honorary members of this society. He described the work of the eminent French *savant*, arguing that the society's estimate of his merits ought not to be influenced by the fact that he was not a friend of Germany, and declaring his personal opinion that the Berlin Medical Society had honoured itself by electing M. Pasteur as honorary member. He suggested that M. Pasteur's obvious aversion to Germany might be accounted for by the circumstances that Strassburg, the town where he had gained his first honours, had changed owners, and that his native district had witnessed one of the most unhappy periods of the war. It is a real comfort for all who dislike the intrusion of political hostility into scientific matters that Professor Virchow seized the opportunity to point out the immortal merits of the deceased. The German lay press, and, unfortunately, a small portion of the medical press as well, have been prompted by the occasional unfriendliness of M. Pasteur's utterances to stop short of an adequate appreciation of this great man. The warmth of Professor Virchow's speech and the ardent approval of his sentiments by the greatest medical society of Berlin sufficiently show that the German medical profession realises the greatness of the loss which science all over the world has suffered by the death of M. Pasteur.

ROME.

(FROM OUR OWN CORRESPONDENT.)

THE SIXTH CONGRESS OF INTERNAL MEDICINE.

Dr. Baccelli's Address.

ON Oct. 22nd the *aula magna* of the University was thronged in every part as his Excellency, Dr. Guido Baccelli, opened with an inaugural discourse the Sixth Congress of Internal Medicine. After a reference to the great International Congress held in Rome at the Easter of last year as encouraging Italy to reconquer her old position in the "foremost files" of medicine, his Excellency indicated the incessant movement, which was not always progress, in the medical world, and insisted that its goal was ever the same: the perfecting of clinical medicine and State medicine, both of them having as basis general and experimental pathology, which must that day be reinstalled in the post of highest honour. "With clinical medicine," he continued, "we cure the individual. With State medicine we conserve the people. The etiology of disease, with its vast horizons and its multiform reciprocation of scientific attempts to unveil it, no longer contemplates merely the morphological indication of pathogenic micro-organisms, but feels the necessity of prosecuting unswervingly the study of toxic products—an arduous undertaking in which, from the first discoveries of Koch, the Italian school pledged itself, as by a military oath, to coöperate." Pointing out how often new and prolific truths reveal themselves at the bedside before the laboratory confirms them by experimental demonstration, his Excellency proceeded: "The scientific movement of the day surges around the cure of infective maladies, and sero-therapy holds the place of honour. Behring's therapeutic conception was justified by events, but criticism, in its severer mood, clipped the wings of a too sanguine expectation. Sero-therapy in diphtheria constitutes to-day the method that numbers most successes; nevertheless, it leaves something to be desired, some material for new studies, so that we may reap the harvest it is capable of yielding. To-day one of our colleagues proposes sero-therapy even in tuberculosis. But a truce, gentlemen, to *a priori* judgments, possibly inspired by sentiments inadmissible in the cool contemplation of facts. In the impartial and severe response we shall have to pronounce before the scientific world let us not forget the famous motto of the 'Accademia del Cimento'—'Provando e riprovando' (by testing and re-testing)." From this his Excellency passed to another prominent theme before the Congress on "the metabolism whose activity in the human organism is at once its conservation and its defence. Of late years, even in other fields of pathology, Italian work, especially in the nervous system, earned fame for its authors and honour for their country. Once and again I have told you that, while respecting all, we should be jealous of our own achievement and not allow the scientific world to hold as of non-Italian origin those truths which had their birth-place in Italy. Some years ago one of our number had to show to Nannyn that what he announced as to the murmurs of the impaired heart had already been taught in an Italian clinique, and to-day we must adopt the same attitude towards some late French doctrine appropriating to itself the discovery of the lines of propagation of mitral murmurs (especially in insufficiency)—a 'discovery' which for thirty years had been a *locus communis* in Italian clinical teaching." Reverting, however, from this vindication of national merit to the brotherhood of science, his Excellency discoursed on the advantages of periodical meetings like the Congress which had brought them together, and concluded, amid loud applause, with the aspiration that *pari passu* with Italy's political resurrection would proceed her rehabilitation in the world of science.

Sero-therapy.

Dr. Pio Foà, Professor of Pathological Anatomy and Bacteriology in the University of Turin, thereupon delivered his report on Sero-therapy. I may summarise his conclusions as follows:—Sero-therapy is the result of patient, systematic

Digitized by Google

research in the laboratory, and is founded on the reaction of a receptive animal organism to an infective agent introduced, like vaccine, by various methods, or on the reaction of the organism to the toxic products of the agent itself. Organisms endowed with natural resistance do not ordinarily react with the production of immunising and curative substances; the most effective reaction is given by the most receptive organisms. Hitherto the soundest results have been obtained by toxic infections, still the latest researches point to obtaining similar effects in septic infections. The notion that every infection is reduced to a simple poisoning and every reaction to the production of an antidote, is, perhaps, too absolute. We must distinguish the specific poisons (diphtheria, tetanus) from those which are not, while the reaction of the organism will possibly be excited either against the poison or against the protoplasm itself of the bacterium. Sero-therapy in diphtheria issues triumphant from the test of practice, and statistics establish for it a distinct diminution of mortality. Sero-therapy in tetanus has proved less efficacious in acute cases. The tetanic manifestations in such cases would indicate deep organic lesions already completed, against which sero-therapy would be unavailing. Still, sero-therapy is an excellent prophylactic. Sero-therapy in typhoid fever and cholera has yet to be tried. The main difficulty, perhaps, depends on the notable difference subsisting between experimental results and the natural course of infections in man. Important experimental studies have been made (and their results recently published in THE LANCET[1]) by Professor Tizzoni and Dr. Centanni on Sero-therapy in Rabies; but we await its more extended application to the human subject. The researches of Viquerat and Marmoreck give promise of the success of sero-therapy in the surgical field through infections by (for example) the streptococcus pyogenes. Dr. Foà's latest studies seem to solve the problem of sero-therapy in the diplococcic infection of the rabbit; he has yet to investigate the problem in animals of greater bulk admitting of the application of the results to man. Sero-therapy (he concluded) ought to be no bar to the development of prophylaxis. Both aim at preventing maladies; and sero-therapy, where it proves efficacious in preventive immunisation, will itself become a prophylactic measure. Dr. Maragliano, Professor of Clinical Medicine in the Genoa school, then took up the subject where Dr. Foà left off, and his views (already to some extent placed before the British Medical Association at its last meeting) may thus be epitomised):—The therapeutic serums, to develop their proper action, require the effective coöperation of the affected organisms. The value of sero-therapy can be determined only by clinical observation. Sero-therapy can manifest its peculiar action as well in acute as in chronic affections. The therapeutic serums hitherto employed in European practice are absolutely innocuous. Sero-therapy, in its clinical applications, has up to the present yielded indeterminable results in the streptococcic and typhoid infections; doubtful results in tetanus; promising results in pneumonia, which only requires a methodical clinical employment of it; positive results in tuberculosis, where it awaits nothing more than the confirmation of a case-list, which already bids fair to be an extended one; and impregnable and truly triumphant results in diphtheria.

Oct. 28th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera Intelligence.

DURING the last week there have been 18 new cases at Damietta and in a village adjoining it, many of them young children, and mostly mild cases. However 7 patients have died during the week, showing that the disease must not be trifled with, though it does not possess any of the alarming symptoms usually seen in the East when cholera first breaks out. At Mansourah some little excitement was caused by a man being found dead on a barge which had just arrived from Menzaleh. As Dr. Kaufmann found in this case the comma bacillus the clothes were burnt, the barge disinfected, and the man's companions were isolated in a tent in a field outside the town, where, after five days, they are all quite well. As this death showed that the disease probably existed at Menzaleh a native inspector was at once sent to seek out any sick there and to start a hospital. His first report now states that he has found 18 sick at Menzaleh and two neighbouring villages, besides which 5 cases have died. Since then Dr. Keatinge has been sent in a steamer to patrol the canal and the villages between Mansourah and Menzaleh, and he already reports that he has discovered 4 suspicious cases at a tiny village called El Kordi on this canal, about one-third of the way from Menzaleh towards Mansourah. He has left a medical man with these 4 cases and all necessary equipment. Dr. Kaufmann has found some cases of cholera in isolated villages of Lake Menzaleh. The whole of the cholera in Egypt is at present confined to two foci, Damietta and Menzaleh, both in free communication with each other, and both considerably behind the rest of Egypt in sanitary progress. At both places there is an abundant supply of good water coming from the Nile below Cairo, and the English irrigation engineer is himself superintending the supply. Of course there has been the usual demand for sanitary cordons, based on the most selfish and illogical reasons, but I glad to say that the Egyptian Government has accepted the advice of its English medical men and has decided, instead of cordons, to establish inspection stations for the examination of those coming from infected districts. In at least two instances temporary blocks on the railway and on a canal were caused by an attempt at a limited cordon, but these have now been removed as it was conclusively shown that their only effect was to impede bales of cotton and commerce generally, while no restriction could be placed on people using other routes, of which in this roadless country there are very many.

Need of Telegraphic Communication.

It is distinctly inconvenient that there is no telegraph between Mansourah and Menzaleh. It has been recommended to lay down a temporary wire, and in the meantime mounted orderlies are despatched every day with letters. There is no panic in the country, and people on the whole are behaving very well. Based on the experience of sixty years, there is a very widespread belief that cholera cannot seriously spread over the country at this time of year.

Mansourah, Oct. 23rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Inspection of "Way Passengers."

FOR the purpose of more effectually protecting the country against an invasion of cholera from Japan the United States Treasury Department established an inspection of passengers on the Pacific Mail Steamship Company's vessels returning from infected ports in that country. This inspection was not limited to passengers bound to the United States, but included also passengers who intended to disembark at Yokohama, or, in other words, "way passengers." The company objected to the action of the Consul at Kobe, who ordered this inspection, and appealed to the Secretary of the Treasury. The decision of the Secretary was that, "for the protection of the through passengers and the people of the country, it is as important that the way passengers, or those who are to stop at the intermediate ports, should be inspected. Otherwise the passengers bound for the United States would always be in danger of contagious and infectious diseases from such uninspected passengers. If persons who take local passage from Kobe to Yokohama, for instance, are exempt from inspection under the law, then for the same reason a shipload of passengers could without inspection be brought from Kobe or some other eastern port to a Canadian port on a vessel coming to the United States." The request to discontinue the inspection was therefore refused.

Results of Municipal Sanitation.

When the Health Department of New York was organised on a scientific basis in 1886 the death-rate was 35·04 per 1000. In 1868 it had fallen to 29·31. In twenty years more the rate was further reduced to 26·60. In 1893 the rate was 23·52, and in 1894 the lowest record was reached since 1814—viz., 21·05 per 1000 inhabitants. The decrease in the death-rate for twenty-five years represents a saving of over

[1] THE LANCET, Sept. 14th, 21st, and 28th, 1895.

3500 lives annually and of over 80,000 lives during the quarter of a century.

The Epidemic of Cholera in Japan.

The medical officer in the United States Consulate at Yokohama, Japan, reports, Sept. 16th, that cholera has now existed in Japan for some five months, that it has been very widely disseminated, chiefly by the troops and coolies returning from the seat of the late war, and is now, or has recently been, present in every province of the empire. There are many centres of infection, so that the total number of disease foci is very great. The present epidemic has a mortality higher than the average, the death-rate for the whole country having, so far, ranged between 65 and 75 per cent., while in certain districts nearly every case has proved fatal. The total number of reported cases is 42,708, and the deaths 28,513.

Life in the Steerage.

The arrangements for steerage passengers on one of the best ocean steamers, the *Campania*, are as follows. The steerage quarters, which are situated on the lower deck, are divided into seven different sleeping apartments for the accommodation of some 700 or 800 passengers. There are separate apartments for the single men, single women, and married couples. The five apartments for the use of the two first-named classes are equipped with from 60 to 110 berths, measuring 6½ ft. by 2½ ft., which are built close together and arranged in tiers of two in the centre of each steerage. These berths are constructed of adjustable galvanised iron piping, thus preventing the accumulation of dirt so common in the case of the old wooden berths. Each passenger is provided with a clean straw mattress and a heavy rough blanket. Each time the steamer reaches port the old mattresses are burned and new ones taken on board, while the blankets are thoroughly washed and cleansed before the return voyage. The quarters for married people are aft, on the lower deck, in a "pocket" on either side of the vessel. Each of these pockets is divided into some twenty state rooms, each containing from two to six berths, which are furnished in the way already described. All the forward steerages extend across the entire width of the deck, are approachable by two entrances, and are well ventilated. The "pockets," which are confined to either the port or starboard side of the vessel, are less roomy and have only one entrance to each. The arrangements for ventilation in the steerage are exceptionally good on this ship. Besides the ventilation obtained from the hatchways and from the large flue ventilators a new ventilating attachment has been placed upon each porthole. It is generally necessary to close the portholes if the voyage is at all rough. This is done by fastening a heavy inch-and-a-half plate-glass cap over the hole, which lets in the light. Just outside the glass cap on the top of the port-hole are several small openings for ventilation. Each one of these openings is provided with a cork so placed on the inside as to allow the air to pass in, but should a heavy wave strike the porthole the force of the breaker drives the cork to its place, closing the openings for ventilation until the wave retreats. The passengers eat their three meals a day sitting on long rows of benches arranged before narrow shelves fastened to the sides of the vessel in the sleeping apartments. Each emigrant is provided on boarding the ship with a plate of heavy crockery, a knife, fork, spoon, and tin cup. These articles each individual is supposed to care for and keep clean during the voyage. After each meal a big pan of water is placed upon the floor in each of the steerages as a common cleansing place for all the dishes. As a matter of fact, however, less than one-third of the passengers ever take the trouble to wash their dishes. Two light and airy hospitals, containing twelve beds each, are situated on the main deck for the use of the sick. The steerage passenger medical officer attends to all cases of illness among the passengers. He is required to punch the inspection card of each emigrant daily after each examination, which is a guarantee to the inspection officers at the Immigration Bureau that the passenger has had no contagious disease. On a certain day during the voyage all the steerage passengers are mustered on deck by order of the ship's medical officer to pass the vaccination examination. If they are found to have been properly vaccinated they receive a certificate to that effect; if not, they are put on one side for subsequent treatment.

Oct. 16th.

Obituary.

LAUNCELOT ANDREWS, M.D., L.R.C.P. LOND., M.R.C.S. ENG., D.P.H. CANTAB.

THE announcement of the death of Dr. L. Andrews, which occurred on Oct. 29th at 22, Cheyne-gardens, Chelsea, will, we know, be received with the deepest regret by all who knew him. Launcelot Andrews was the eldest son of the Rev. W. R. Andrews, rector of Teffont Ewyas, Wilts. He was educated at Haileybury and St. Bartholomew's Hospital, where he held the appointments of house physician, house surgeon, ophthalmic house surgeon, and assistant electrician. Some five years ago he started practice in Chelsea, and for so young a man succeeded remarkably well. His death was due to a very rapidly growing malignant tumour of the abdomen. He was most popular among all with whom he had to do at the hospital. A hard worker in everything he did, always cheerful and apparently never tired, his untimely end — he was only thirty-one—will be a source of sorrow to his many friends as well as to his patients. He leaves a widow and one child.

ARTHUR MEREDITH WHITEHEAD, M.B., C.M. ABERD.

WE regret to announce the death of a well-known and highly respected colonial practitioner, Dr. Whitehead of Petone, Wellington, New Zealand, who first arrived in the colony about nine years ago and passed away on Aug. 30th at a comparatively early age. He was the son of a Nottingham alderman and was born in 1861. Having made up his mind to follow the medical profession, he became a student at the London Hospital and also attended classes at Aberdeen University, where he graduated in 1883. After a short experience of practice in Nottingham he made several voyages as surgeon of a passenger steamer plying to China, and in 1886 settled in Petone, which was thenceforward to be his home, although he made a long visit to England in 1894, returning to the colony in the beginning of the present year. The funeral was conducted with military honours, in presence of a great assemblage, including Government officials, military and naval officers, and representatives of various public bodies. Dr. Whitehead has left a widow and a young family.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Litthauer, "Physicus" of the Fifth Municipal District of Berlin, and a well-known local authority on sanitary matters. — Dr. Schütte, formerly Director of the Elizabeth Children's Hospital, Berlin.

DIPHTHERIA IN LONDON.—The returns for London in the matter of fatal diphtheria last week were, it is true, somewhat better than in the week immediately preceding, wherein 76 deaths from that disease had been registered. But even last week the registered deaths numbered 61, or 22 in excess of the corrected decennial average of the similar week of the years 1885-94. The malady is widely distributed over the metropolis, finding place in districts stretching from Greenwich, southward and eastward, to Enfield on the extreme north of the "outer ring." Of the 61 deaths, 7 belonged to St. Pancras, and 6 each to Islington, Poplar, and Greenwich sanitary areas. The cases finding their way into hospital are far from being the whole of the attacks arising from week to week, and much dissatisfaction is being felt by sanitary authorities at the small percentage of removals. The admissions last week were 115 in number, against 90, 102, and 115 in the three preceding weeks. The patients remaining under treatment for this disease on Saturday last numbered 675. In Greater London the deaths for three weeks in succession have been identical—namely, 27; and of this total last week there were 9 in West Ham, 7 in Edmonton, and 3 in Willesden registration areas. In the Edmonton district there has been a state of panic on account of the disastrous outbreak of the disease in the Waltham parishes, the sanitary condition of the places affected being seriously called in question.

UNIVERSITY OF ABERDEEN. — The following candidates received the degrees of Bachelor of Medicine and Master in Surgery on Oct. 26th:—

Affleck, James, Scotland.
Auden, Arnold William Montford, B.A., England.
Ayatullah, India.
Bell, William Jarvis, America.
Bray, Ernest James, Australia.
Bruce, John, Scotland.
Campbell, Robert Brown, Scotland.
Carmichael, Edward William Scott, Scotland.
Coates, John Mandall, Scotland.
Crawford, James Mansfield, Ireland.
Crerar, Donald, Scotland.
Dewar, David Fitchie, England.
Dixon, James Herbert, England.
Elliott, George Christopher, England.
Evans, Alfred Thomas, Wales.
Evans, David, Wales.
Evans, William, England.
Fernandes, Ramsden Walker Luis, England.
Fitzgerald, William, New Zealand.
Fleming, Archibald Nicol, Scotland.
Fothergill, George Algernon, England.
Gibson, Francis Maitland, B.Sc., Scotland.
Guthrie, Roger Christian Lingard, Scotland.
Hewison, John James, M.A., Scotland.
Hewison, William, Scotland.
Hirst, John, England.
Johnson, Walter, England.
Lall, Chaman Chandu, India.
Lamb, James Henry, Scotland.
Leighton, Gerald Rowley, England.
Livingston, George Robert, Scotland.
Love, Alexander Mayne, Ireland.
M'Rae, George Douglas, Scotland.
Martin, James Sackville, Ireland.
Massey, James, Ireland.
Masson, George Henry, Trinidad.
Moore, William Andrew Wylie, Ireland.
Munn, Patrick James, Scotland.
Ogilvy, Stewart Grant, Scotland.
Park, Alexander John, Australia.
Pentland-Smith, Archibald Lumsdaine, M.A., B.Sc., Scotland.
Purves, Robert Black, Scotland.
Roberts, John Howard Digby, India.
Rodger, Robert Stuart, England.
Roe, Robert Lloyd, Ireland.
Roger, David, Scotland.
Ross, Alfred Peter, England.
Saldanha, Luis Cupertino, India.
Scott, James George Campbell, Scotland.
Sibbald, Bernard Ian Graham, Scotland.
Smith, Sydney Harold, England.
Theobalds, Arthur John Arundel, England.
Thompson, Charles Gurney, England.
Twidale, Frederic William, India.
Vos, Jacob William de, Cape Colony.
Williams, Lewis Arthur, England.
Wills, Frederick Telemachus, British Guiana.
Wilson, William Henry, England.

FOREIGN UNIVERSITY INTELLIGENCE.—*Marburg:* Dr. Joseph Disse of Halle has been appointed Professor of Anatomy.—*Pisa:* Dr. Minati, Professor of Midwifery and Gynæcology, has retired.—*Rome:* Dr. Galassi, Professor of Special Pathology, has retired.

BOURNEMOUTH MEDICAL SOCIETY.—The annual meeting was held on Oct. 25th at the Hotel Mount Doré, when the committee's annual report and the balance-sheet were submitted. Mr. C. H. W. Parkinson, the retiring President, gave up the chair in favour of Mr. D. C. Embleton, President-elect. The following officers were elected for the ensuing year: Vice-President, Mr. A. G. S. Mahomed; Treasurer, Dr. Kinsey-Morgan; Secretary, Dr. H. G. Lys; Librarian, Dr. S. L. Clift; Committee, Mr. A. C. Kemble (Poole), Dr. W. H. L. Marriner, Dr. C. D. Muspratt, and Dr. F. W. Ramsay. The annual dinner was held after the meeting, at which twenty-three members and seven guests were present.

A NEW WORKHOUSE INFIRMARY.—An entirely new infirmary, a mortuary of noteworthy completeness, and a disinfecting chamber are approaching completion at the Guildford workhouse. The former consists of two blocks in duplicate united by the administrative buildings. Each block is 210 ft. long and from 24 ft. to 64 ft. wide, and consists of three storeys. On the ground floor are two separation wards of four beds each, a long ward for the aged and infirm with twenty beds, and two wards containing altogether seventeen beds for children and special patients; a day-room, offices, and exercising yard being attached. The separation wards only rise one storey; in other respects the first floor of each block follows the ground plan, while above are the nurses' day and night quarters. The staircases are of concrete, and heat is supplied by hot-air stoves. The administrative buildings include a large kitchen, surgery, and attendants' room, but the general cooking will be undertaken at the workhouse, with which a corridor connects the infirmary. Lying-in wards are over the administrative block. An "observation block" for suspicious cases—two wards and attendants' rooms—is built at a short distance. The mortuary consists of a viewing-lobby separated from the dead-house by a glass partition, as in the Morgue, a post-mortem room with operating-tables, and a hearse-house. A disinfecting chamber has also been built to provide the means of fumigating clothing by gas. The total accommodation of the new buildings is some 160 beds.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen, having passed the necessary examination for registered practitioners, have been admitted Licentiates of the College:—Edward Barker Barber, L.S.A. Lond., and Henry Ernest Watts, L.S.A. Lond.

ROYAL BRITISH NURSES' ASSOCIATION. — The first sessional lecture of the season will be given at 17, Old Cavendish-street, W., on Friday, Nov. 22nd, at 8 P.M., by Dr. Louis H. Parkes, medical officer of health, Chelsea, on the Importance of breathing Fresh Air.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—On Monday, Oct. 28th, in the theatre of the school, Dr. Howship Dickinson distributed the certificates of honour given to students who had gained scholarships, exhibitions, and prizes during the year. The recipients were: Mr. Walwyn Thomas, £100 Exhibitioner and Treasurer's Prizeman; Mr. Sidney Smith and Mr. Frank Morley, Brackenbury Prizemen in Medicine and Surgery respectively; Mr. E. T. Fison, Special Certificate of Honour in Medicine; Mr. R. A. Cooper, Brodie Prizeman; Mr. H. S. Barwell, Henry Charles Johnson and Proficiency Prizeman; Mr. R. E. Drake-Brockman, Brodie Prizeman; Mr. C. R. Keyser, Sir Charles Clarke's Prizeman; Mr. T. M. Neatby, Proficiency Prizeman; Messrs. H. S. Pendlebury, H. G. Deller, and Howell Evans, Entrance Scholars in Science; and Messrs. T. C. English, H. A. Chaplin, L. F. Cope, and Lawrence Jones, Entrance Scholars in Arts. Addressing the students at the close of the ceremony Dr. Dickinson warned them against the danger of becoming one-sided—a danger to be avoided by a legitimate degree of indulgence of an Englishman's natural taste for sport and by the cultivation of the great masters of English literature. For the works of Milton, Addison, and Gibbon he claimed special attention.

THE DIFFUSION OF SMALL-POX — There was some slight increase of small-pox in London last week as compared with the week preceding. The totals of removals had in the three weeks ended Oct. 19th been respectively 17, 9, and 7, but last week they were 14 in number. There was one registered death, that of an unvaccinated infant of six months of age removed from Chelsea to the hospital ship *Atlas*. According to returns from the Metropolitan Asylums Board and from Highgate Small-pox Hospital the patients remaining under treatment for small-pox numbered on Saturday last 114, a further slight decline on the total of 119 in the preceding week. The cases occuring in the week ended last Saturday were very unevenly distributed over the several days; on Friday, for example, no attack was reported. There is still an outcry respecting the position of the hospital ships at Long Reach, their proximity to populous districts being considered a distinct danger to the community, and much has been said locally as to the desirability of the removal of the vessels from their present moorings. The General Purposes Committee of the Metropolitan Asylums Board have suggested that plans be prepared for temporary small-pox buildings at Joyce Green farm, Dartford, and the Small-pox Hospitals Committee have advised the appropriating of the whole or part of Gore Farm Small-pox Hospital at Darenth for convalescent fever patients. In the provinces some small stir has been caused at Kington by reason of the charge of £3 10*s.* on account of the damage done to a cab in which a doubtful case of small-pox was removed to the workhouse, no proper ambulance and no proper hospital having apparently been provided. Both Manchester and Salford in recent weeks report freedom from small-pox cases, and from Oldham we learn that only a single, and that non-fatal, attack of small-pox was heard of in the fortnight ended Oct. 19th. The locality of Wigan seems to have suffered somewhat recently, but good use is being made of the local hospital arrangements. Small-pox is not extinct in Dublin, but the subject of the isolation provision to be made for that disease is just now receiving an amount of attention far beyond that given to the actual presence of the malady itself. Much comment has been passed on the workhouse shed in which convalescing patients have been housed at Kilmainham, and loud outcry has been raised against the continuance of small-pox hospitals in the midst of the city. The question has been pronounced upon by the medical staff of the Irish Local Government Board in a manner to cause the advocates of city small-pox isolation provision to hesitate before committing the city to further danger from the treatment of small-pox near aggregations of population.

THE SANITARY INSPECTORS' ASSOCIATION.—The first ordinary monthly meeting of the Session 1895–96 will be held to-day, Saturday, Nov. 2nd, 1895, at 6 P.M., at Carpenters' Hall, Throgmorton-avenue, E.C., when the annual address of the chairman will be delivered by Mr. Henry Thomas, chief sanitary inspector of Bermondsey, and applications for election to membership will be considered, after which there will be the usual members' conference.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—A meeting of the South-Western Division was held at Wonford House, Exeter, on Oct. 15th. Dr. Morton, Dr. Rutherford, Dr. McLean, and Mr. Laslett were elected members of the association. Dr. Deas opened a discussion on the Uses and Limitation of Mechanical Restraint as a Means of Treatment. Dr. Deas's able and succinct remarks were followed by a prolonged and interesting discussion. Dr. Morton read notes on Three Cases of Spontaneous Gangrene. It was agreed that Dr. Macdonald's paper on the Nursing Staff should be the subject for discussion at the next meeting. The spring meeting was fixed for Tuesday, April 14th, 1896. The members afterwards dined at Pople's New London Hotel.

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—The first meeting of the session was held on Oct. 26th at St. Marylebone Infirmary, the President, Mr. J. R. Lunn, F.R.C.S. Edin., being in the chair. There were several visitors, amongst whom were Dr. Colcott Fox, Mr. Geo. Stoker, and Dr. M. H. Spencer. Dr. Colcott Fox delivered a short address on Ringworm, explaining the varieties, the differences of their growth, and the treatment to be adopted. He deprecated the constantly recurring craze for some new parasiticide, which invariably ended in disappointment, chiefly because the proper method of application was not intelligently carried out. He then briefly described the irritant treatment, recommending the use of an ointment containing the red oxide of mercury.—Dr. F. S. Toogood (Lewisham Infirmary) pointed out the danger of producing permanent baldness by over-irritation.—Mr. Geo. Stoker described the method, and exhibited his apparatus for the treatment of ulcers of the leg by the oxygen bath.—Mr. J. R. Lunn exhibited cases of pemphigus exfoliata, pemphigus rash produced by the internal administration of iodide of potash, functional chorea, ankylosis of lower jaw relieved by operation, tabetic feet, congenital pemphigus, and Charcot's disease of the shoulder-joint. Mr. Lunn also showed a card specimen of aneurysm of the thyroid axis cured by operation.

LITERARY INTELLIGENCE.—Mr. W. B. Saunders of Philadelphia announces the early issue of the "American Year-book of Medicine and Surgery," edited by Dr. George M. Gould, the author of the latest excellent "Dictionary of Medicine," whose experience peculiarly qualifies him for the preparation of this work, not only to review the contributions to American journals, but also the methods and discoveries reported in the leading medical journals of Europe, thus enlarging the survey and making the work characteristically international. These reviews will not simply be a series of abstracts, nor will they be retrospective of "news" one or two years old, but the treatment presented will include only what is new as regards the year in question. The work will be profusely illustrated.—"Clinical Illustrations of the Diseases of the Fallopian Tubes and of Tubal Gestation," by Charles J. Cullingworth, M.D. Durh., F.R.C.P. Lond., is the title of a work which will shortly be issued by Messrs. Rivington, Percival, and Co. The work, which consists of a series of drawings with descriptive text and histories of the cases, is designed to assist medical practitioners who have few opportunities of seeing the diseased parts after removal from the body, but within whose experience the diseases often come. The coloured drawings have been made while the specimens were still fresh. A feature of the work will be the frontispiece, in which an attempt has been made to depict the Fallopian tubes as they are found in the living subject as distinct from drawings made from dissecting-room specimens pinned out for display without regard to the natural relations of the various adjacent parts.—"Haydn's Dictionary of Dates," the most universal book of reference in a moderate compass in the English language, and a work indispensable to literary men, is, we are glad to note, about to pass through a new edition brought down to the autumn of 1895. This, the twenty-first, edition will contain some 1230 pages, 12,000 articles, and 140,000 dates and facts. Messrs. Ward, Lock, and Bowden, Limited, are the publishers.

THE Royal National Pension Fund for Nurses received £22,500 last week.

MR. W. H. JALLAND, M.R.C.S., of York, has accepted the office of Sheriff of the city for the ensuing year.

AN ASYLUM FOR CARDIFF.—A conference of delegates from the Glamorgan County Council and the borough councils of Cardiff and Swansea was held at Cardiff last week in reference to the Bridgend Asylum. It was stated that 400 out of the 1000 patients now under treatment were from Cardiff, and it was decided that Cardiff should separate from the union of the asylum authorities and construct an asylum of its own.

A PUBLIC ABATTOIR FOR BRISTOL.—At the meeting of the Bristol Sanitary Committee held last week a report was presented by the medical officer of health (Dr. D. S. Davies) and the assistant medical officer (Dr. Dowson) upon Slaughter-houses. It stated that there are eighty-five slaughter-houses in Bristol; forty-four are unfit for that purpose owing to structural derangements, unsuitability of locality, and neglect of common sanitary precautions, twenty-one are passable, and only twenty can be classed as fit; only one complies with the recommended rule of the Local Government Board that the abattoir should be 100 yards from a dwelling-house. There is only one meat inspector in Bristol, and he has to look after the fruit and vegetables as well. He cannot do all this thoroughly, and so there are facilities for the disposal of unsound meat which are practically beyond the control of the inspector. Dr. Davies mentioned that Liverpool, with an abattoir, had six meat inspectors. Financially the abattoir would be a benefit, as the majority of these in other large towns pay from 4 to 6 per cent. The report concluded with a strong recommendation for the erection of a public slaughter-house. The chairman of the sanitary committee proposed, and it was carried, that it was desirable to provide a public slaughter-house, and that the engineer be requested to give particulars of the working, cost, revenue, &c. of such structures, and to suggest a suitable site. The slaughter-houses in Bristol are evidently in a most unsatisfactory state, and it is gratifying to see that the sanitary committee are anxious to carry out the suggestion of their medical officer of health for the erection of a public abattoir. As Bristol is a large meat-distributing centre it is impossible for one inspector to do his work thoroughly. This can easily be remedied by the employment of additional inspectors.

ROYAL ALBERT ASYLUM.—The annual meeting of this institution for idiots and imbeciles of the northern counties was held on the 25th ult. at Southport, the chair being occupied by the mayor, Alderman Dr. Wood. The report stated that there were 542 patients in the asylum—370 boys and 172 girls. The great majority came from Lancashire and Yorkshire. During the year there had been 64 admissions, 56 discharges, and 17 deaths. There was great difficulty in making it understood that it was "an educational establishment, and that it would be a sheer waste of resources, with the full and varied staff of teachers and trade instructors, to receive hopeless cases of idiocy." In moving the adoption of the report Sir John Hibbert said there were 5000 weak-minded persons in the northern counties under twenty years of age, of whom one-half were capable of being trained in such an institution as theirs. They had accommodation for 600 patients, and with an increase in the subscriptions they could fill up the vacancies. Those admitted were put through a course of seven years' training, and there were few cases in which great improvement did not take place. Of the 56 discharges 20 were much improved, 24 materially, 8 slightly, and only 4 not improved. Many discharged patients earned their own living (one was receiving 23*s.* a week at the trade he learned at the asylum), and during the year two enlisted in the army, of whom good accounts had been received. He contrasted the scanty provision made in this country for these cases compared with what was done in America and in many European countries. In Norway and Sweden there are, in addition to several special institutions, classes in connexion with the public elementary schools for feeble-minded pupils; and during the past year the London and the Leicester School Boards had made special provision for these cases, but Sir John Hibbert did not know that this was done in any of the northern counties.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

AMESS, JAS., M.B., Ch.B. Melb., has been appointed a Public Vaccinator for Richmond, Victoria, Australia.

BATEMAN, C. E. G., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Workhouse and the Walsingham Sanitary District of the Walsingham Union.

BOULTON, A. E., M.R.C.S., has been appointed Medical Officer of Health for the Horncastle Rural Sanitary District, vice H. George.

CARMICHAEL, W. J., M.B., C.M. Aberd., has been appointed Surgeon and Agent to the Coastguard at Colliston and Medical Officer for the Parish of Slains, vice Dr. Jamieson, resigned.

CHARLES, RHYS P., has been appointed Analyst for Neath.

DAVENPORT, H. D., L.R.C.S. Irel., has been appointed a Public Vaccinator for the district of Hunterville, New Zealand.

EDWARDS, NORMAN FOX, of Bowdon, Cheshire, has been appointed House Physician to the Swansea Hospital.

EVANS, ARTHUR HENRY, has been appointed Resident Obstetric Assistant to the Westminster Hospital.

FLEMYNG, G. G., M.D., B.S. Dubl., has been appointed Medical Officer for the Downham Sanitary District of the Ely Union.

GARSTANG, THOS. W. H., M.R.C.S., has been appointed Medical Officer of Health to the Bucklow Rural District Council (late Altrincham Rural Sanitary Authority).

GIBBS, F. R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Eighth Sanitary District of the Wycombe Union.

GLEDDEN, A. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Miners' Association at Minmi, New South Wales.

GOODE, W. H., M.D., Ch.M. Dubl., L.K.Q.C.P. Irel., has been appointed an Official Visitor to the Hospitals for the Insane at Gladesville and Callan Park, New South Wales.

GORDON, W., M.A., M.D., B.C. Cantab., M.R.C.P., has been appointed Physician to the West of England Eye Infirmary, Exeter.

HOOD, A. J., M.B., Ch.M. Glasg., has been appointed Honorary Physician to the Sydney Hospital, New South Wales, vice Huxtable, deceased.

HOUMAN, ANDREW, M.R.C.S. Eng., has been appointed Health Officer for Williamstown, Victoria, Australia, vice Johnston, resigned.

JAMES, PHILIP, F.R.C.S., has been appointed Surgeon to the Wellington Hospital, New Zealand.

JOLLY, R. W., M.R.C.S., has been appointed Medical Officer of Health for the City of Peterborough, vice W. E. Paley.

JOYCE, A. F., M.B., Ch.B. Melb., has been appointed Public Vaccinator for East Brighton, Victoria, Australia.

KIDD, A. E., M.B., C.M. Edin., has been appointed Resident Medical Officer in the Dundee Hospital for the Sick Poor.

LITTLEJOHN, T. H., M.B., C.M. and F.R.C.S. Edin., D.P.H., has been appointed Medical Officer for Scarborough.

MORGAN, H. DE R., M.A. Oxon., M.R.C.S., L.R.C.P. Lond., has been reappointed Medical Officer of Health for the Cockington Urban District Council.

MORLEY, H. W., M.R.C.S., L.R.C.P., formerly Assistant House Surgeon, has been appointed House Surgeon to the Royal Portsmouth Hospital.

MUTCH, F. R., M.D. and C.M. Aberd., has been appointed Surgeon to the Samaritan Hospital for Women, Nottingham, vice E. B. Truman, resigned.

NAYLOR, A. G. E., L.R.C.P., L.R.C.S. Edin., has been appointed Health Officer for Dunmunkle Shire, North Riding, Victoria, Australia.

PATTINSON, H. A., L.R.C.P. Irel., M.R.C.S., has been appointed Medical Officer of Health for the Seaton Urban Sanitary District.

POWELL, T. P., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Deputy District Vaccination Officer by the Retford Board of Guardians.

SHEWEN, ALFRED, M.D. Lond., M.R.C.S., has been appointed an Official Visitor to the Hospital for the Insane at Parramatta, and the Lincensed House for the Insane at Cook's River, New South Wales, vice Huxtable, deceased.

SWALLOW, F. McD., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the Penistone Rural Sanitary District.

THROWER, M. R., L.R.C.P., L.R.C.S. Edin., has been appointed a Public Vaccinator in South Australia.

TIBBETTS, T. M., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health by the Quarry Bank Urban Council, vice W. H. Thompson.

WEST, WALDEMAR S., M.A., M.B., B.C. Camb., has been appointed Resident Medical Officer to the Royal Hospital for Diseases of the Chest, City-road, London, E.C.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon. Salary £100 per annum, with rooms and attendance (not board).

CATERHAM ASYLUM (under the Metropolitan Asylums Board).—Second Assistant Medical Officer. Salary £120 per annum, rising £10 annually to £150, with board, furnished apartments, attendance, and washing. Applications to the Clerk to the Board, Chief Offices, Norfolk-street, London, W.C.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon. Salary £80 per annum, with board, washing, and residence in the house.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, 32, Soho-square, London.—Resident Medical Officer for six months. Board, residence, laundry, and an honorarium of 10 guineas.

ROYAL PORTSMOUTH HOSPITAL.—Assistant House Surgeon, for six months. Board and residence provided, and an honorarium of 15 guineas.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant House Surgeon for six months. A gratuity of £10 will be given if found satisfactory.

ST. MARY'S HOSPITAL FOR SICK CHILDREN AND MEDICAL MISSION DISPENSARY, Plaistow, London, E.—Resident Medical Officer. Salary £80, with board, washing, and attendance. Applications to Chairman of Committee, Rev. T. Given-Wilson, Plaistow.

SUNDERLAND INFIRMARY.—House Physician. Salary £80, rising £10 annually to £100, with board and residence.

TOWNSHIP OF TOXTETH PARK.—Junior Assistant Resident Medical Officer for the Workhouse Infirmary. Salary £75 per annum, with board, washing and apartments. Applications to the Clerk to the Guardians, 15, High Park-street, Liverpool.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY, Whitehaven.—House Surgeon. Salary £120 per annum, and £30 per annum for Dispensing, with furnished apartments and attendance.

Births, Marriages, and Deaths.

BIRTHS.

CARVELL.—On Oct. 27th, at Grove-villas, Wanstead, the wife of J. Maclean Carvell, L.S.A., of a son.

CLOSE.—On Oct. 18th, at Strafford House, Boston, the wife of Henry A. Close, Deputy-Inspector-General R.N. (retired), of a daughter.

EDWARDS.—On Oct. 27th, at 55, Harley-street, W., the wife of T. Swinford Edwards, F.R.C.S., of a daughter.

HARRIS.—On Oct. 29th, the wife of John Russell Harris, M.D. Brux., of Adam-street, Adelphi, of a daughter.

HAYNES.—On Oct. 27th, at Lansdowne-place, Leamington Spa, the wife of Fredk. H. Haynes, M.D., of a daughter.

HOWELL.—On Oct. 23th, at Cleeve House, West Hill, Wandsworth, the wife of Thos. Arthur Ives Howell, of a son.

HUTCHINSON.—On Oct. 25th, at Haslemere, Surrey, the wife of Roger J. Hutchinson, M.R.C.S., L.R.C.P. Lond., of a daughter (Marjorie).

MAITLAND.—On Oct. 26th, at The Terrace, Haslar, Gosport, the wife of Percy E. Maitland, Surgeon R.N., of a son.

MARRIAGES.

BAKER—YULE.—On Oct. 26th, at Trinity Church, Finchley-road, Hampstead, J. H. Baker, M.B. Durh., of Tavistock-square, W.C., to Florence, second daughter of J. B. Yule, of Netherhall-gardens, Hampstead, N.W.

BOSTOCK—HADEN.—On Oct. 24th, at the parish church, Sidmouth, Robert Ashton Bostock, Surgeon-Captain 2nd Scots Guards, to Caroline Mary, daughter of Mrs. Haden, of Cardigan.

LYTTLE—LEWIS.—On Oct. 23rd, at St. Catherine's Church, Pontypridd, James Shaw Lyttle, M.D., M.Ch., M.A.O. Irel., Clifynyd, Pontypridd, to Edith Mary, eldest and only surviving daughter of the late Rev. Moses Lewis, Vicar of Llanwonno.

REID—WESTON.—On Oct. 23rd, at St. Mary's, Stafford, Charles Reid, M.B. Aberd., of Stafford, youngest son of the late David Reid, of Aberdeen, to Ada Mary, eldest daughter of Edward Francis Weston, of Stafford.

WEST—DEAR.—On Oct. 23rd, at St. James's Church, Pokesdown, Bournemouth, Richard Milbourne West, M.R.C.S., L.R.C.P., eldest son of H. A. West, of Ryde, Isle of Wight, to Ellen, daughter of F. C. Dear, of Bengoe, Hertford.

DEATHS.

ANDREWS.—On Oct. 29th, at Cheyne-gardens, Launcelot William Andrews, M.D. Lond., eldest son of the Rev. W. R. Andrews, aged 31.

BATESON.—On Oct. 24th, Robert Sander Bateson, Deputy-Surgeon-General I.M.S., of Upna Ghur, Lancaster, in his 64th year.

HUTCHINSON.—On Oct. 26th, at St. Andrew's, Bedford, James Alexander Caldwell Hutchinson, M.D., Surgeon-General, I.M.S. (retired), aged 67.

MACKENZIE.—On Oct. 29th, at Gloucester-terrace, Hyde-park, Inspector-General Sir William Mackenzie, K.C.B., C.S.I., M.D., Honorary Physician to the Queen, late Madras Medical Service, aged 84.

MILLS.—On Oct. 30th, at his residence, 12, Museum-street, Ipswich, William Partridge Mills, M.D., J.P., aged 79 years. No cards. No flowers.

REDFORD.—On Oct. 26th, at Cricklewood, N.W., George Redford, F.R.C.S., aged 79.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2 30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. President's Inaugural Address. Mr. C. J. Boyd Wallis: (1) Discolouration of Teeth after using Hyd. Perchlor: (2) Some Remarks on Amalgams.—Mr. J. Main Nicoll: (1) Ptosis of Dental Origin; (2) Fracture of the Maxillary Tuberosity during the Extraction of the Second Molar Tooth. The Discussion on "The Immediate Regulation of Irregular Teeth" will be resumed.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

TUESDAY.—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Papers:—Dr. Snow: The Non-existence of Round-celled Sarcoma as a Distinct Class of New Growth.—Drs. Garrod and Hopkins: On the occurrence of large amounts of Hæmatoporphyrin in the Urine after the administration of Sulphonal.—Mr. Beadles: The Relation of Biliary Calculi to Malignant Disease of the Liver.—Mr. Jackson Clarke: Dermoid Tumour of the Testis.—Mr. Edmunds: Cystic Accessory Thyroid. Card Specimens:—Mr. Beadles: Ureter Obstructed by Calculus.—Dr. Willcocks: Perihepatitis and Thrombosis.—Dr. Walsham: Pulmonary Stenosis.—Mr. Edmunds: Myxoma of Breast.

WEDNESDAY.—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Papers:—Prof. G. E. Curatulo (introduced by Dr. Griffith): On the Influence of the Removal of the Ovarian Metabolism in connexion with Osteo-malacia.—Mr. J. Bland Sutton: On a case of Tubo-uterine Pregnancy; Primary Intra-peritoneal Rupture; Recovery.—Dr. A. E. Giles: A case of Uterus Didelphys, with Remarks on the Clinical Importance of this Malformation. Special General Meeting. Confirmation of Revision of Chap. vi. of the Laws.

THURSDAY.—NEUROLOGICAL SOCIETY OF LONDON.—8.30 P.M. A Clinical Demonstration (Drawings and Patients) of the Tropho-neuroses of the Skin, more especially Herpes and Morphœa, at Mr. Jonathan Hutchinson's Museum, 1, Park-crescent.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Mansell Moullin: Supra-pubic Cystotomy and Prostatectomy in cases of Multiple Calculi.—Mr. Golding Bird: A case of Intussusception through a patent Meckel's Diverticulum.—Mr. Langton: A case of Osteopsathyrosis (Fragillitans Ossium) in which, after firm union of several fractures had taken place, disunion occurred in some several years afterwards.—Dr. Althaus: A case of Brain Tumour successfully healed by Internal Medication.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Great Portland-street, W., 8 P.M., Dr. Whistler: Syphilis of the Pharynx and Larynx.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Alcoholic Insanity.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

HOSPITAL FOR CONSUMPTION &c. (Brompton).—Mr. R. J. Godlee: Surgical Anatomy of the Chest.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—5 P.M. Dr. Morgan Dockrell: Lichen Planus.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Eccles: Cases of Hernia.

Digitized by Google

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Mr. W. A. Lane: Selected Surgical Cases.—National Hospital for the Paralysed, Bloomsbury, 2 P.M., Dr. Bastian: Cases in the Hospital.—Central London Sick Asylum, Cleveland-st., 5.30 P.M., Mr. J. Hutchinson: Cases in the Wards.
FRIDAY.—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M. Prof. Crookshank: Actinomycosis and Glanders.
SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Percy Smith: Insanity with Syphilis.
ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—Dr. Morgan Dockrell: Syphilis.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.
Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.
We cannot prescribe or recommend practitioners.
Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."
Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*
We cannot undertake to return MSS. not used.

BAREFACED USURPATION.

A CORRESPONDENT has drawn our attention to the following legend, which appears on the letter-paper of a certified masseuse:—

MISS F——, 108, —— Road,
M.B.M.A., LOND., —— Street,
CERTIFIED MASSEUSE, ——.

He says that at first sight he thought that the letter in question emanated from a Bachelor of Medicine and Master of Arts in the University of London. He has since found that the affixed initials to Miss F——'s name are meant to imply that that lady is a Member of the British Massage Association, and he wants to know what we think of such methods. We have no hesitation in saying that to place the initials M.B.M.A. Lond. after a name is to imply that the person in question holds the degrees with which our correspondent credited Miss F——. The fact that there is no gap between the B and the M is a trifle that might escape anyone's notice (how often do we see M.B., C.M. printed without proper spacing?) and the addition of the word "Lond." seems specially designed to carry out the imposture. We consider that the heading to this letter-paper constitutes, as we have termed it, a barefaced usurpation by a masseuse of the style and title of a graduate in Arts and Medicine of London University.

Mr. Charles Blair.—The best account of the Burmese hairy family is to be found in Yule's "Mission to the Court of Ava" (Smith, Elder, and Co., London, 1858), pp. 93, 94, 95, where a portrait will be found Some of the descendants of this family were, we believe, living at the court of King Theebaw at the time of our recent annexation of Upper Burmah.

Cardiffian.—The volumes have no pecuniary value worth mentioning.

"WHAT IS LIFE?"

To the Editors of THE LANCET.

SIRS,—I can heartily sympathise with your correspondent, "Only a Medico," who asks the above question after having perused various writings on the subject in THE LANCET. That of Dr. Lionel Beale is of great interest, but I do not quite follow him in one particular. He says that life is not the product of any physical change, but is an independent principle, or a distinct "guiding and directing agency." Now, in the analogous case of the mind there are also the two similar theories—the one that mind is an emanation from the brain; the other that it is an independent principle, remaining when the body decays and becoming an immortal spirit. In like manner, as regards the vital principle, or "vitality," I ask, What becomes of it when a vegetable or animal is burned or otherwise destroyed? I should like the lecturer's clear opinion or belief in this matter—demonstration he cannot give—so that I may more fully seize the thread of his argument.

I am, Sirs, your obedient servant,
Oct. 27th, 1895. ENQUIRER.

FEES.

To the Editors of THE LANCET.

SIRS,—In October, 1894, I attended a woman in her confinement (who had engaged me for a fee of one guinea). After the child was born I found she had adherent placenta. This I endeavoured to remove, but during removal I found she was in a collapsed condition. Having brought her round, after a time I operated, removing part but not all. She then collapsed again. I informed the nurse that the case was serious, and told her that I should call in another practitioner. I saw the husband, and sent him for another medical man, upon whose arrival we administered chloroform and removed the placenta. After three weeks' attendance the patient recovered I sent my account in with an additional charge of half-a-guinea—the fee I paid the other practitioner for his attendance. The husband refusing to pay, I reluctantly summoned him for the debt. The county court judge at the hearing allowed the guinea fee, but disallowed the half-guinea paid under the circumstances mentioned above.

If this is a correct decision, what are we to do in such circumstances with a serious case? Are we to call in another practitioner, pay his fee, and bear the loss ourselves; or are we to leave the patient without further advice? The net result to me has been that after attending the case before, during, and after confinement I receive a guinea, out of which I have to pay my colleague 10*s.* 6*d.*, leaving me with the same amount as a reward for my anxiety and trouble.

I am, Sirs, yours faithfully,
Oct. 24th, 1895. T.

*** In our opinion the hardship of these cases, which are constantly occurring, might be avoided, if the medical man, when undertaking to attend a midwifery case for, say, a guinea, made it clear that for that fee he would only attend for the confinement and ten days after, and that it would not include attendance beyond that time, if it should prove necessary, or the services of another medical man if the case should be one requiring another practitioner on account of some complication. In this actual case when the medical man saw the husband and obtained his sanction to call in another practitioner he should have explained that the latter would have to be paid separately. At the same time we sympathise with our correspondent, who has had shabby treatment meted out to him.—ED. L.

M.D., in writing of the Dentists Act, attributes grossly unprofessional conduct to a brother practitioner. He will understand that we cannot print his letter without knowing to whom he is referring, and that even then a question would arise as to the utility of the publication.

M.D.—Technically, the School Board never demands a certificate. It is only the magistrate who does so. If "M.D." is unwilling to give a certificate he had better refer the parents to the parish doctor.

Mr. J. Allison Smith.—There is no such fund at our disposal or elsewhere. Particulars concerning THE LANCET Relief Fund can be obtained from Mr. E. Davis, THE LANCET Office.

Dr. White is advised to do nothing.

"WANTED, AN EXPLANATION OR A SUGGESTION."

To the Editors of THE LANCET.

SIRS,—I should suggest the probability of the case described in THE LANCET of last week being one of so-called "scar keloid" which sometimes follows variola pustules, syphilides that have destroyed the skin, and the scars of burns. I have known of a similar case in a child six years of age, where two firm, freely movable pink masses with well-defined projections made their appearance in the cicatrices shortly after vaccination. They were about an inch long and three-quarters of an inch wide, and gave rise to no subjective symptoms. The family history was good; but there seemed to be a predisposition on the part of the skin to such formations, as a similar mass developed in the same case after the healing of an incised wound on the leg. The case was successfully treated by electrolysis, a stout needle being used and multiple punctures made in all directions and in the tissues for a space about the growths. I am, Sirs, yours truly,
Halifax, Oct. 26th, 1895. H. LAWRANCE GILL, M.D.

"THE BIRMINGHAM LUNACY PROSECUTION."

To the Editors of THE LANCET.

SIRS,—I beg to correct the impression in THE LANCET of Oct. 26th. The number of hours was *six*, not sixteen.—Yours truly,
Birmingham, Oct. 30th, 1895. F. R. EVANS.

During the week marked copies of the following newspapers have been received:—*Huddersfield Chronicle, Midland Times, Manchester Guardian, Straits Budget (Singapore), Liverpool Echo, Dover Express, Dudley Herald, South Wales News, Suffolk Chronicle, North Wales Chronicle, Leicester Daily Mercury, Sussex Daily News, Hastings Times, Birmingham Chronicle, Guardian, Sheffield Independent, Hinckley Times, Medical Record (New York), Tolnes Times, Glasgow Herald, Dublin Evening Telegraph, Western Mercury, Nottingham Daily Express, Bradford Observer, Cork Constitution, Brighton Gazette, Scotsman, Citerer, Leeds Mercury, Builder, Portsmouth Times, Citizen, Architect, Yorkshire Post, Cyclist, Bristol Mercury, Sanitary Record, Perthshire Advertiser, Family Doctor, St. Mary's Hospital Gazette, Technical World, Pioneer Mail, Guy's Hospital Gazette, Midland Sun, Australasian Medical Gazette, Graye Standard, Islington Gazette, Anglo-Celt (Cavan), Evening Chronicle (Newcastle), Birmingham Daily Post, &c., &c.*

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières Paris.

An Address
ON
THE ADVANTAGES OF OXIDATION.

Delivered before the West London Medico-Chirurgical Society on Oct. 4th, 1895,

BY A. SYMONS ECCLES, M.B. ABERD.,
PRESIDENT OF THE SOCIETY.

[AFTER a few words of thanks to the Society for selecting him as their President, Dr. Eccles said:]

Gentlemen,—There are certain phenomena of life so familiar by reason of their constant occurrence within, around, and about us that I would venture to suggest the possibility of forgetting them if they were not so frequently brought before us in all their significance by some disturbance in regularity which we recognise as pathological; and at the risk of being tedious I would ask you to permit me to discuss very superficially, and of necessity inadequately, so well-established and unassailable a physiological doctrine as is embodied in the title of this address, "The Advantages of Oxidation." My excuse for referring to a subject, which you may regard as too obviously belonging to the very A B C of physiological truth to require any suggestion on my part, is that for the last two or three years I have been endeavouring in a very small way to learn for myself some lessons bearing on the oxidation processes in the human body. If, then, you are needlessly reminded of elementary physiological facts at the outset of this address you will perhaps forgive me for alluding to them in order to clear the way for those suggestions which I shall offer as the result of personal investigations—lessons in a measure self-taught, and maybe replete with error, inasmuch as they are only the crude and clumsy attempts of one who has not at his disposal the knowledge and skill of a scientific physiological chemist.

The first fact—or, so to speak, letter—of the physiological alphabet which it appears to me we should bear in mind while discussing the advantages of oxidation in regard to the human body, in health and disease, is this, that whereas plants by a reduction process build up simple bodies of small molecular value and stable composition into complex combinations of high molecular value and unstable constitution, animals, on the other hand (the human body, for instance), by oxidation break up the complex combinations of atoms formed by plants into bodies of much simpler constitution and of greater stability, and in this combustion process heat, work, and other forms of energy are evolved. The second letter of our physiological A B C to which I would draw your attention is that the end products of these oxidation processes are carbon dioxide and water, the result of non-azotised substances, and urea, which may again be decomposed into carbon dioxide and ammonia, the result of azotised matters or proteids. May I venture to suggest that most of the work done in the human body is performed, so far as we are yet aware, by the combustion of the carbohydrates, while the wear and tear of the organism itself are represented by the nitrogenous waste matters, the end product of complete combustion being urea? It may be that this suggestion will not hold good, but that, to continue my simile, I am attempting to construct from our physiological alphabet a word which is mis-spelt and does not exist as a physiological truth; but on reference to Professor Michael Foster's work I find that my notion, at any rate in regard to muscular work, is not so far-fetched as it might appear to be, for he compares the special contractile carbon-hydrogen substance of a muscular contraction to the charge of a gun, the products of its combustion being carbonic and sarcolactic acids, while the real living material of the fibre may be compared to the gun itself, which, however, is constantly undergoing change in excess, according to Foster, of mere wear and tear.

Since a large proportion of the oxidation processes carried on in the human body occurs in the muscular system, it may not be unprofitable to note briefly the present state of our knowledge in regard to the series of chemical events taking place in an active muscle. We find that the products of incomplete oxidation of both nitrogenous and non-nitrogenous matters are always in excess, while, except in cases of severe and almost unique over-fatigue, the formation of urea—i.e., of completely oxidised proteid matter—is not increased. It is to the accumulation of partially oxidised waste products within the muscle that we must attribute the fatigue, and that impotence to continue work after a certain time which supervenes on muscular exercise. It appears that the quantity of nitrogenous material oxidised is the same in an active and passive muscle, but during contraction such a quantity of oxygen is used up in the combustion of the hydrocarbons that insufficient oxygen remains for the complete oxidation of the nitrogenous matter; so, instead of urea, we have other substances resulting from muscle waste—default of oxygen leading to incomplete combustion and the consequent formation of uric acid and creatinine, substances which may be regarded as the insufficiently oxidised precursors of urea. But this incomplete oxidation is also shared by the hydrocarbons, for, although we find seven times the amount of carbon dioxide formed in an active muscle over and above the amount produced in the passive organ, there are certain products of incomplete combustion derived from hydrocarbons rendering the reaction of the fatigued muscle acid instead of alkaline. The most constant of these non-nitrogenous fatigue products is sarcolactic acid, and it is probably to the accumulation in the system of both this and the incompletely oxidised nitrogenous products of muscular activity that we may attribute the aching weariness of over-fatigue experienced by persons unaccustomed to exercise. It must be remembered, however, that, although evidences of excessive acidity and of leucomaines may be found after over-exercise in the urine of persons habitually sedentary, no such phenomena present themselves in the urine of individuals who are in training. In other words, it is possible to improve the processes of intra-organic oxidation and to render them more complete by means of a course of regular and systematised exercise, which will induce increased amplitude of respirations, augment the volume of blood passing through the muscular system, and favour the combustion of fatty tissue.

But oxidation does not only take place in the muscles, for we know that it occurs in the blood itself, in the glandular structures, and, as Ehrlich has shown, in the cells of all the tissues, especially in those of the brain, liver, and heart, where processes of oxidation and reduction are constantly going on.[1] I cannot hope to add much to the knowledge already placed at our disposal by Gautier,[2] who first gave the name leucomaine to alkaloids appearing during life in the tissues of animals. His researches, with those of Brieger, Bouchard, Liebreich, and Pouchet on the Continent, and of Thudichum in our own country, have resulted in the isolation of these toxic substances in healthy and morbid urine. It has been shown that they are physiologically produced in our bodies and eliminated by the bowels, kidneys, skin, and lungs. They exist in the blood where they accumulate if for any reason they are not got rid of, and under these circumstances we suffer from the effects of auto-intoxication; but there are two distinct methods by which nature provides that we should not poison ourselves with our own venom—viz., the elimination of these toxines by the organs of excretion and their destruction by oxygen. Of these two methods the most important is the process of oxidation, for most of these leucomaines are very readily oxidised, and, as Gautier has shown, it is by the constant renewal of oxygen that they are burned up and made to disappear, such of them as are not destroyed by combustion being more readily and easily eliminated after oxidation. Under normal conditions only a very small proportion of leucomaines is found in the urine; but if anything should interfere with the due oxygenation of the blood, or if the oxygen therein contained should be used up for the oxidation of other materials, then we find that there is a remarkable increase of leucomaines in the urine, pointing to an excess of these toxines in the blood, so that it would not be far wrong to describe the morbid condition of some patients as "leucomainæmia." In 1882 Bouchard demonstrated the presence of animal alkaloids in healthy urine and that they were greatly in excess in cases of infectious fevers, particularly in typhoid fever; while Pouchet observed them in the urine in certain cerebral maladies without fever. It is, however, in the class of disease so admirably described by Bouchard as "maladies per ralentissement de nutrition"—e.g., anæmia, chlorosis, gout,

Digitized by Google

glycosuria, neurasthenia, and uricacidæmia—that we find the clearest evidence of insufficient activity in the oxidation processes, with excess in the urine of the products of incomplete oxidation. Speaking for myself, I would venture to assert that many phenomena of functional nervous disorders are primarily due to this deficiency of oxidation; that, as a consequence of this insufficient combustion, toxic substances accumulate in the blood and give rise to the train of symptoms—dyspeptic, myelasthenic, encephalasthenic, and emotional—which we classify or generalise under the term neurasthenia.[3] Whether these toxic matters are alkaloids or not, they appear to be capable of producing more or less profound disturbance in the functions of nutrition; and it may be that these extractives, nitrogenous and incompletely oxidised, exist side by side, as Gautier has suggested, with alkaloids which have been isolated and crystallised. The method employed for the detection of leucomaines in the urine is that which is described by Professor Alexander von Poehl of St. Petersburg in his communication on Oct. 10th, 1892, to the Academy of Sciences of Paris on the Rôle of Spermine in Intra-organic Oxidations, and is set down by him as follows. "To 100 c.c. of urine are added 25 c.c. of hydrochloric acid, HCl (sp. gr. = 1124), and 10 c.c. of a decinormal solution of phosphotungstic acid. The precipitate is composed of leucomaines as phosphotungstates." Von Poehl goes on to say that he estimated the nitrogen of this precipitate by the method of Kjeldahl, and in cases in which albumin or peptone was present these substances were eliminated by precipitating them with phosphotungstic acid in the presence of acetic acid. In examining urine for the presence of leucomaines I have closely followed the directions given by Von Poehl as above, save in regard to the Kjeldahl process for the estimation of nitrogen, which is of too complicated a character for ordinary clinical use. In every case the whole of the urine passed during twenty-four hours available for testing purposes has been collected, and from the mixed urine so obtained the necessary quantity for examination has been taken. (See Tables I. and II.) In some cases several observations have been made on the urine passed in the same twenty-four hours, and the morning and evening urines in a few cases have been separately tested.

Each specimen has been tested for albumin by the heat and nitric acid test, and in some cases after filtration by the acetic acid and ferrocyanide of potassium test. Similarly in every case the biuret test for peptones has been employed. Albumin has not been detected in the urine in any of the cases here recorded; in those in which the presence of peptone was indicated by the biuret test the urine has been filtered after the peptone was precipitated by the phosphotungstic acid in the presence of acetic acid, and the filtrate so obtained has been treated with hydrochloric and phosphotungstic acids in the proportions indicated by Von Poehl. In estimating the quantity of the precipitate of phosphotungstates each filter paper has been separately weighed before use, and from the total weight of the dried precipitate and filter paper after filtration the weight of the filter paper has been subtracted. The filter papers employed were those usually regarded as chemically pure, and the weights were taken by means of Becker's balance sensible to $\frac{1}{2}$ milligramme. Every precaution was taken to avoid error in carrying out the tests as far as they go, but I am aware that they are open to objection on the score of accuracy in the description of the precipitate. It is maintained by scientific chemists whom I have consulted in the matter that substances other than leucomaines and ptomaines are precipitated from urine by the reagents employed in the proportions cited, and one of my friends has been good enough to perform control experiments with Hofmeister's and other tests for animal alkaloids given by Von Jaksch in his work on Clinical Diagnosis.[4] In trying several of these reactions it was found that the results differed materially, and it appears therefrom that the excessively complicated nature of some of the bodies present in healthy urine, and still more so in urine under pathological conditions, renders it well-nigh impossible to be sure as to what one is doing. Under these circumstances lengthy investigation would be necessary to show where the differences lie, and the work would be very complicated. Attempts have been made to eliminate the source of possible error, but without any marked success. Von Poehl, however, is my authority for the methods employed, and to use his own words, "le précipité se compose de leucomaines à l'état de phosphotungstates." The urea has been estimated by the ureameter of Southall, and it is interesting to note that in comparing the relation between the weight of the phosphotungstate precipitate and that of the urea as estimated for the same twenty-four hours it will generally and almost invariably be found that they are in inverse ratio. When the proportion of the precipitate is high the estimated quantity of urea is low, and *vice versâ*. The exceptions to

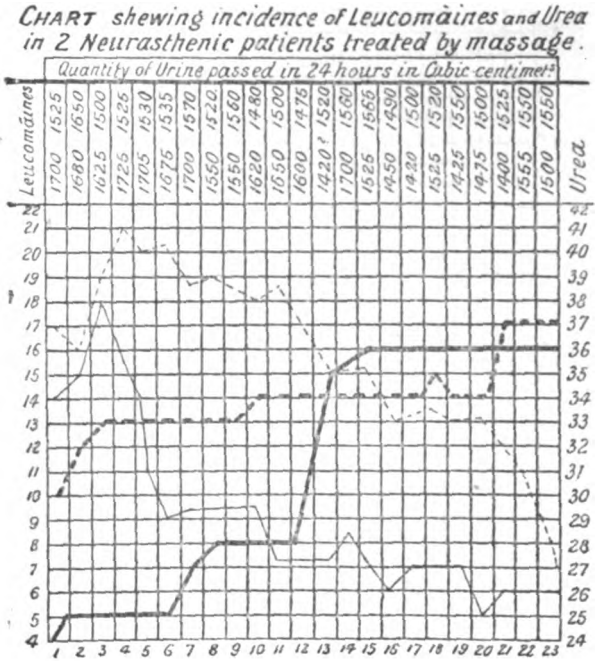
this have been so rare that they may be regarded as unimportant.

In regard to Table III., it must be borne in mind that the amount of urea has been computed from the volume of nitrogen gas evolved. But this nitrogen may represent urea *plus* other nitrogenous urinary constituents, normal and abnormal; therefore, if my experiments are correct, the presence of leucomaines appears to interfere with the elimination of azotised waste product, for even when the phosphotungstate precipitate is heavy the volume of nitrogen does not seem to increase proportionately. While, then, I do not desire to lay great stress upon the comparative quantity of the leucomaine precipitate on the one hand, and that of urea computed by the hypobromite test on the other, as the conclusions drawn therefrom may be based on error, there still remains the clinical fact that when Von Poehl's test shows a heavy deposit certain conditions of disturbed function appear to be associated therewith, and it would appear that these functional derangements may be regarded as symptoms of retention poisoning. That uric acid is not the only factor in the production of the symptoms which I believe to be due to the presence of incompletely oxidised bodies in the system is shown by the fact that in many cases there is distinctly low tension.

Now in every case of healthy urine the amount of the precipitate (which for the purpose of this address I shall assume to be correctly deemed to be composed of leucomaines or of these alkaloid *plus* other products of nitrogenous waste incompletely oxidised) is very small compared with the quantity thrown down from morbid urine. Again, the amount of urea, although it varies somewhat in health and disease, is usually greater in the former case. In a case of melancholia or profound depression, in which an attack of influenzâ for the time being was attended by complete remission of all the mental symptoms, the patient during the period of pyrexia losing all despondency, dread, and insomnia, it was most remarkable to see the fluctuation in the amount of leucomaines before, during, and after the pyrexial attack. (See Chart I.) During the first four days of the disease the temperature rose from 97·8° to 102·5° F., with an intermission of one degree on the evening of the third day. From this point it gradually declined, reaching the normal on the ninth day and never again rising, though occasionally subnormal. The quantity of urea excreted was 26 grammes on the first day. From this point the quantity rose considerably with the temperature, reaching 40 grammes on the fifth day, and declining thence to 33 on the twelfth day, between which point and 35 grammes it remained. The quantity of leucomaines was 17 grammes at the beginning; by the third day it had risen to 21, whence it declined steadily to 13. During the following twelve days it remained at this point or below, save that on two occasions it rose to 15 and on one dropped to 10. On the seventeenth day it suddenly fell to 9·3. Those who are familiar with cases of nervous depression often meet with those of intermittent melancholia in which sometimes with regularity, at others irregularly, the patient presents all the features of most profound depression and mental morbidity, with abject inability to believe that there is any hope of betterment or of avoiding catastrophe on one day, and shortly after, without apparent cause, the demon of misery, irritability, and dejection is supplanted by cheerful freedom from all mental depression and physical malaise. How are we to account for these hitherto inexplicable variations in the subjective symptoms of one and the same individual occurring within a few hours? I believe that the explanation will be found in the ebb and flow of the tide of toxines manufactured and accumulated in the system. The habits of these persons are often sedentary, or tend to become so under the influence of the weird sensations in the head, the vague disorders of the digestion, and the semi-incoördination of the limbs from which they suffer. On examining the urine in such cases, before I was acquainted with Von Poehl's test for leucomaines, I often noticed the presence of oxalates and urates in excess and the small excretion of urea, in one instance the amount per diem of this last substance falling as low as 24 grammes. Since I have employed Von Poehl's method only two opportunities have arisen for noting the incidence of leucomaines in persons suffering from paroxysmal neurasthenia. In both cases the attacks of mental and physical exhaustion have come on without any cause assignable by the patients. In each case vertical and occipital headache, insomnia, mental agitation, hopelessness, and emotionalism have been attended by extreme physical languor and general aching weariness in the back and limbs. Both occurred in otherwise healthy men leading active lives, and certainly in one there was no psychical or physical cause for the sudden supervention of neurasthenia. In the other, possibly overwork of a sedentary

CHART I.



nature may be regarded as a determining factor. Now on examining the urine on each occasion of recurrence of the nervous symptoms a heavy precipitate of leucomaines was observed. At the commencement of treatment by vigorous massage, rest, a light nutritious diet, and mild saline aperients the amount of leucomaines excreted at first increased, but in the first week there was a decrease in the precipitate, which gradually fell in the course of three weeks in one case, and five in the other, to a small quantity, no

Digitized by Google

greater than has been observed in health, while the urea excretion increased. (See Chart II.) *Pari passu* with these changes in the urinary conditions the nervous symptoms of these patients improved and the attack passed off. Now it may be quite fairly alleged that since in the one case complete remission had occurred without any treatment on more than one occasion credit is not to be too readily given to the means employed for the oxidation and elimination of the toxines; yet in face of the evidence in the other case which I shall lay before you, I think that incomplete oxidation of toxines having been recognised during the attack, which passed off with a diminution of their appearance in the urine, it may be conceded in the light of the future history of this patient that

CHART II.

the advantages of oxidation were fully established in his case. This patient, who had been almost entirely incapacitated for his usual occupation during five years by reason of constant breakdown, mental and physical, has kept himself in good health by following my *régime* in regard to exercise. Before he came under observation he had led a very sedentary life, never taking any exercise worth speaking of. During the last two years he has been free from his old enemy, only rarely consulting me—I think thrice only—for slight occipital headache. This happy issue out of his affliction I attribute to the fact that he is constantly employing his leisure in doing those things which are requisite and necessary as well for the body as the soul. He plays lawn-tennis, fences, sculls, and rides according to the season of the year, and has lately developed a very pretty taste for golf. In other words, he is fostering the processes of oxidation initiated by massage and kept up by healthy, vigorous exercise.

It would be easy for me to multiply instances from my case book illustrating the advantages of oxidation in cases of anæmia, glycosuria alternating with uricacidæmia, and other maladies which are obviously conditions associated with incomplete oxidation, in which the promotion of the oxidation processes by the employment of massage, athletic and mechanical exercises, and the use of red bone marrow or injections of spermine, has been attended by the happiest results; but time will not permit, and I will only cite one case which has recently come under my notice fully bearing out the advantages of oxidation in auto-intoxication. A very vigorous, robust friend, who is one of the most athletic of muscular Christians I have ever met, was prevented by an accident from carrying out his usual round of healthy exercise. He straightway fell into a melancholy, peevish condition and consulted me. We devised means for repairing the damaged ankle and I bade him resume his accustomed pastime. While awaiting the opening of the shooting season he accepted an invitation to a country house which for some reason fell through, and my patient, disappointed of his lawn-tennis, became more irritable and felt himself much aggrieved. In his urine I had found ample evidence of deficient oxidation, and suggested various exercises possible in town, of which he would have none; but one morning he arrived in my consulting room radiant and glowing with good health and spirits, when I found that he had taken a leaf out of Mr. Toole's book in the play of *The Upper Crust*. You will perhaps, remember that the gentleman of sudden fortune whose part is played by Mr. Toole, after being annoyed by the snubs of his aristocratic guests, sticks his thumbs into his armholes and truculently announces, "That rascal Grubbins didn't touch 'is 'at to me this mornin'; I'll go and give 'im something." My friend, in much the same frame of mind, having received an annoying letter among his morning correspondence, went forth and hired a pugilist for a twenty minutes' "mill," whence he came back to me announcing where he had been. All the irritability and despondency had been worked off in self-defence, and due oxidation had been re-established. The next day there were only traces of leucomaines in the urine. (See Table III.)

TABLE III.—*Effect of Pugilistic Exercise on a Healthy Person temporarily Sedentary.*

Amount of urine.	Leucomaines.	Urea.	Condition.
	Grammes.	Grammes.

1275 c.c.	6·9	33	Exercise.
1625 c.c.	13·2	35	Cheerful.
1560 c.c.	10·0	38	Quite well.

Gentlemen, at the outset I warned you that my remarks would assume a suggestive, not a constructive character. Now what I am going to say will be speculative rather than suggestive, so that it may fairly be regarded as unpractical and therefore valueless; but we who are not always able to verify our opinions, and who carry out the work of our lives and base most of our practice on what, after all, is only opinion, know that, however valuable scientific certainty must be, there are times when unconscious knowledge, medical instinct, intuition—call it what you will—comes to our aid and guides us to a correct decision, why and wherefore we are never able to formulate. This confession of a fact, which we all recognise even if we will not acknowledge it, must be my excuse for the following speculations. Granted that there is a great family likeness between the toxines due to physiological processes and those of bacterial origin, that both may be anaerobic and by oxidation will be rendered easier of elimination, does it not seem probable that in most cases, if not in all, the presence of pyrexia denotes the existence of toxæmia, and fever is only a vigorous and sometimes over-energetic method of nature to oxidise these matters and so get rid of them either by burning them up or by making them ready for excretion? Under these circumstances high temperatures, so long as they are not hyperpyrexial, may not be altogether without beneficence. If I do not weary you, let us note for a moment the parallelism between the prodromatous symptoms of the acute fevers and the usual concomitants of chronic functional nervous disorders. In both we find general malaise, rachialgia, prostration, nervous and muscular, disordered digestion, headache, derangements of sleep, and mental disturbance. Nor does the similarity end here, for in not a few instances of so-called nervous maladies we meet with pyrexia, as in the hysterical hyperpyrexia known to us all. May not the fevers of over-fatigue, of hysteria, and of zymotic disease proceed from one and the same cause? Not, indeed, of common origin, for in the one set of cases we are dealing with auto-intoxication without the intervention of bacterial agencies; in the other the infection is introduced from outside. How often we see the temperature of little children running up to a great height as the result of some transient disorder of digestion and subsiding equally rapidly under the administration of a little dose of

Digitized by Google

calomel, at once an intestinal disinfectant and an eliminant. Is not the hyperpyrexia in these cases an effort of nature to oxidise, and thus aid in the elimination of leucomaines or ptomaines absorbed from the gastro-intestinal tract? There is, however, another small point in reference to disturbance of digestive function to which I should like to allude before passing on to the brief consideration of other conditions pointing to the importance of oxidation. In cases of chronic disease depending on, or associated with, deficient oxygenation, we find dyspeptic symptoms markedly present, and of these one of the most frequent causes is butyric fermentation. Now, as you are aware, while lactic fermentation is aerobic and normal, when not excessive, butyric fermentation is always abnormal and anaerobic. This condition is very common among anæmic persons and those suffering from wasting maladies; sometimes, also, I believe, it is not uncommonly present in pneumonia. Under such circumstances the administration of the so-called ozonised water, which is really a solution of peroxide of hydrogen, proves valuable in checking the fermentation process. I have not myself had opportunities of testing the value of what our French neighbours manufacture and describe as "l'eau oxygénée" in acute maladies; but in the digestive troubles of anæmic, chlorotic, and obese subjects I have found this preparation exceedingly useful; indeed, I am not at all sure that I have not seen benefit arise from the simple practice of swallowing air, although under ordinary conditions of flatulent dyspepsia, due rather to lactic than to butyric acidity, we all know how greatly the discomforts of a recumbent patient are increased if we do not teach them to take liquid nourishment without swallowing quantities of air. May not the introduction of oxygen into the stomach prove useful in arresting the suffering which anaerobic fermentations set up, greatly adding to the already heavy burden which the patient with pneumonia has to bear? This gastric complication in acute maladies and its local treatment may be a comparatively trivial matter regarded in the light of the more serious and dangerous conditions arising out of deficient oxidation; yet, since we are not only engaged in the endeavour to save life and arrest disease, but also to assuage suffering and relieve pain, it may not be altogether beneath your notice.

I suppose there are few who would object to the general statement that all anæmic patients are constipated; but is it not equally true that most sufferers from constipation are anæmic or present signs of deficient oxidation? Every day clinical observations appear to point to the existence of more or less coprostasis as the cause of the bloodless condition. Compare the headache, foul tongue, depression, and irritability produced by a large dose of quinine with the similar conditions accompanying constipation and the absorption of toxines arising therefrom. Ehrlich's observations on the effects of quinine upon living cells have shown how these are deprived of their oxygen and reduced from a state of amœbic activity to an inert mass of almost spherical protoplasm. Now it has been shown that leucomaines and ptomaines are very readily oxidisable, or, in other words, that they are also like quinine, powerful reducing agents, and if we remember that oxidation and reduction processes are constantly alternating within the cells it is easy to understand how readily this rhythm may be upset by the presence in the blood of these poisons. On this point it would be interesting to obtain further information as to the relationship which I believe exists between the presence in the blood of toxic substances and the pale, almost waxy appearances associated with long-continued habitual constipation. We know that the large intestine takes a great share in the work of absorption. After the richer elements of the food have been elaborated, prepared, and absorbed by the stomach and small intestine, in the splendid economy of nature that which remains is so dealt with that we may regard the colon as the "chiffonnier," the mass of material finding its way into this last receptacle, being, as it were, carefully picked over, slowly and laboriously turned and stirred, until nothing that can be utilised for the purposes of nutrition is suffered to escape. When this purpose, however, takes too long in doing the chemical processes assume a putrefactive nature, and thus follows the introduction of poisonous in place of nutritive material. Now one feature in the character of ptomaines and leucomaines is their greed for oxygen. They are among the most easily oxidisable nitrogenous bodies, so when they reach the blood, either by absorption from the intestines or as the result of tissue waste, it is not difficult to explain the anæmia, blood starvation, and deficiency of oxygen which we recognise as salient symptoms in the condition of so many who consult us. The same struggle for life which has been so brilliantly described by the Russian scientist as existing between phagocyte and microbe would appear to occur chemically rather than physically between the invading horde of leucomaines and the army of peaceful red corpuscles engaged in the labour of obtaining, conveying, and giving up the oxygen necessary for the life of the tissues. How often do we not see the history of communities simulated—nay, almost repeated—in the physiological story of our own bodies? The unstable, half-starved, ill-conditioned nomad sweeps down from his mountain fastnesses upon the hard-working, somewhat sleek, and certainly unwarlike pastoral population of the plains. So it is with these conditions of deficient oxidation; not only do we find bodies formed which are in themselves evidences of oxygen poverty, but when formed and absorbed from without they not only seize upon the surplusage but deprive the blood and tissue cells of their fair share of oxygen. In examining the blood of persons suffering from constipation who have also exhibited anæmic and neurasthenic symptoms the corpuscular value is not often found to be decreased, but the proportion of hæmoglobin is usually below the normal in all such cases, so that in conditions of bloodlessness due to auto-intoxication we do not find at first a diminution in the numbers employed for conveying oxygen to the tissues, but a deficiency in their load; thus the anæmia is qualitative rather than quantitative. Under these circumstances elimination alone will not suffice to restore the health of the patient, but means must be taken to promote also oxidation processes in themselves favourable to the destruction or evacuation of the offending matters.

It is interesting to note in connexion with the processes of oxidation the swing of the therapeutic pendulum of the day. We have our attention on the one hand constantly drawn to the virtues of numerous antipyretics of coal-tar origin, all of which owe their action to their reducing qualities, while on the other hand we are beginning to recognise the value of animal extracts, the majority being remarkable for their potency as oxidising agents. I cannot help thinking that we are apt to be too prone to avail ourselves of the antipyretic series, while perhaps we are not plucky enough to make as much use as we might of the oxidising properties of organic extracts. We find that retention of toxines, the products of incomplete oxidation, means prostration, depression, and general misery, whereas their elimination is attended by cheeriness and restoration to comfort of body and peace of mind, as in the cases already cited, where influenza arrested melancholia and a bout with a prize-fighter restored equanimity.

I have tried to suggest some of the advantages of oxidation and the probable relationship between various obscure nervous states and deficient oxygenation. In our practice to-day we are called upon to treat a generation which is beginning to escape from the hereditary consequences of mercury and bleeding prescribed to their forbears. Evidences of attenuation are growing fainter, robust and sthenic types are not so rare as heretofore. The "Lydia Languish" of yesterday is being ousted by "Mary Fenwick's Daughter" of to-day; but we still meet with examples in both sexes of persons who, in spite of the fact that they were evidently meant to take plenty of healthy exercise and to breathe deeply draughts of fresh air, will not find time or opportunity for duly oxygenating their blood and oxidising their tissues. It is our duty to enforce on our patients the paramount necessity of caring for their bodies, and in a race so addicted to out-door pursuits and so fond of sport it is not often that difficulties are placed in our way. But spasmodic efforts to perform the allotted task make pain of pleasure, and too vigorous exercise after a long spell of inaction does more harm than good. The combustion processes must be maintained with regularity as well as vigour. We must endeavour to foster the chemical interchange between the blood and the tissues necessary to health by such means as will induce the introduction of sufficient oxygen and the more active oxidation of organic matters, raise the temperature, increase the secretions, and stimulate respiration and circulation.

FOOTBALL CASUALTY.—In a match, on the 26th ult., between the Excelsior and Brighton Teachers' teams, a player in the former team fractured his clavicle.

GLEANINGS FROM SURGICAL PRACTICE.

By THOMAS BRYANT, M.Ch., F.R.C.S. Eng. & Irel.,
CONSULTING SURGEON TO GUY'S HOSPITAL; PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, &c.

II.[1]—Rupture of the Liver.

This injury, although always grave, is not of necessity fatal, for it is capable of being repaired. Preparations (Nos. 1948[a] and 1951[b]) and drawings in the pathological museum of Guy's Hospital clearly illustrate the truth of this observation. When recovery follows this injury such cases have been usually classed and treated as examples of traumatic peritonitis, their true nature not being at the time revealed. The amount of injury to the liver must, however, when life has been saved, always be limited, and the case otherwise not seriously complicated. In a general way, when a liver or spleen is lacerated death from shock and hæmorrhage speedily follows the injury. In exceptional cases the patient may survive a few days. Thus, out of nine consecutive cases of ruptured liver admitted into Guy's Hospital five died rapidly and three (men) survived three, seven, and nine days respectively.

Case 8. *Fracture of the ribs on the right side, with rupture of the liver; death on the fourth day.*—An old man aged seventy-one was admitted into Guy's Hospital with fracture of some of his right ribs, but without any abdominal symptoms. Bronchitis ensued, and death occurred on the fourth day as a result. After death a rent was found in his liver, which was filled with blood-clot and reparative material, which, if he had not had other complications and had possessed more reparative power at the bank of health to draw upon, would doubtless have completely closed up. There was no blood in the peritoneal cavity.

Case 9. *Injury to the head and abdomen; death from secondary hæmorrhage from ruptured liver.*—A man aged forty-five fell from a cart when intoxicated, and the wheel was said to have passed over his head. Intoxicated to an extreme degree, he was admitted, under Mr. Birkett's care, into Guy's Hospital, presenting neither collapse nor symptom of either abdominal or even cranial mischief beyond some hæmorrhage beneath the right conjunctiva. He was put to bed and soon fell asleep, and on the following morning, with the exception of the hæmorrhage into the orbit, no signs of internal mischief could be detected. Rest, however, in the horizontal position was strictly enjoined; but to this he would not submit, and thirty-six hours after the accident he got up, walked about, and, with a sudden pain in his side, fell back and died. After death a fissured fracture of the skull was found passing across the right orbit, without brain complication; and about a pint of blood existed in the peritoneal cavity, which had evidently escaped from a severe laceration of the liver—a mass the size of a man's fist, situated in the right lobe, having been nearly separated. The right kidney was also fissured on its convex surface, and the fissure was covered with coagulated blood. In this case the man clearly died from rupture of the liver, which at the time of the accident was not associated with either collapse or bleeding; the injured mass, however, subsequently became separated by the patient's walking, and death from secondary hæmorrhage was the result. Had this incident not taken place recovery might have been possible.

Case 10. *Ruptured liver; death on the twenty-eighth day.*—A woman aged forty-two, much given to drink, was admitted into Guy's Hospital under my care on June 23rd, 1876, having been brought in by the police in a state of intoxication after she had been injured in a drunken row. When seen by the house surgeon, besides a wound of the lip and some head bruises, there were indications of local injury over the right lower ribs, where she had apparently been kicked, and a rough diagnosis was made of fracture of these ribs, for which she had her side carefully strapped up. The woman apparently went on very satisfactorily for seven days, when chest symptoms appeared, involving both lungs, and within a week she became very ill, so that she died with chest complications on the twenty-eighth day. At the necropsy the bronchial tubes in both lungs were found to be full of mucus, and the right lung was in a state of grey hepatisation, particularly at its base. The liver weighed fifty-four ounces, and in it there was a large abscess which occupied the greater part of its right lobe; the abscess extended up to the diaphragm, which formed its upper wall and below came within half an inch of the under surface of the liver. The contents of the abscess were broken-down liver structure, blood, and pus. It seems tolerably clear that in this case the abscess formed as a consequence of injury to the liver and of effusion of blood into its structure; and it seems also probable that if the woman had been in better health repair from the injury might have taken place.

Case 11. *Ruptured liver; death on the eighteenth day.*—A man aged twenty-nine was admitted into Guy's Hospital after having received a kick in the region of his liver. He was collapsed on his admission, but soon rallied and complained only of local pain. In a few days symptoms of peritonitis appeared of a localised and chronic nature, and the man sank on the eighteenth day. After death a fissure two inches long and one inch deep was found in the anterior edge of the liver along the fissure for the gall-bladder; this rupture was full of blood-clot, and the tissues about were matted together with reparative material. The gall-bladder was also ruptured to the extent of three-quarters of an inch in the line of the liver, and the edges of the ruptured walls were inverted. There was no bile in the gall-bladder, and no evidence of any having been extravasated. The opening in the gall-bladder was sealed with lymph. In this case the possibility of ultimate repair being secured might reasonably have been entertained, under the most favourable circumstances, if a suspicion only of the nature of the case had been excited in the surgeon's mind who had it in his charge; even as it was nature had done much to repair the mischief which had existed.

Case 12. *Ruptured liver; fractured right lower rib; laceration of the stomach; death on the nineteenth day from peritonitis.*—I must quote one more case to illustrate this part of my subject, for I know of no better example of ruptured liver and complications in which nature's efforts of repair were so nearly successful. A man aged thirty-seven was admitted in 1867 into Guy's Hospital under the care of the late Mr. Hilton, having been crushed between the buffers of two railway carriages applied respectively to the epigastric region and back. As an immediate result of the accident he fell insensible when released, but he recovered his senses in a few minutes and was soon admitted into Guy's Hospital cold and speechless. When put to bed he retched a little, but did not vomit, and as reaction appeared he complained of epigastric pain and liked to rest on his left side. It was made out at the time that the ribs of his right side below the fourth were fractured, but no other diagnosis of injury was framed. His urine was natural. He soon complained of thirst, but on taking some milk it was rejected, but without blood. In two days he had much improved and took a small piece of meat. His bowels also acted naturally. He complained, however, of pain across his chest and of some tightness at the pit of his stomach. His respiration was quiet and he had no cough. The abdomen was slightly distended. On the seventh day his bowels became loose, but he did not pass blood in his stools. His respiration also became thoracic. On the eleventh day the abdomen had become more distended; on the fourteenth this had increased, and a pleuritic rub appeared over the left lower ribs (uninjured side); on the sixteenth day he wanted more food; and on the nineteenth he died as if choked. At the necropsy the right ribs were, as suspected, found to be fractured, and the right pleura was full of serous fluid compressing the lungs. The peritoneal cavity contained some stringy lymph which was blackened from blood which had been mixed with it. There was lymph also about the liver of a yellow saffron colour. The liver was adherent to the diaphragm, and on its upper surface, about its centre, there was a rupture to the extent of two inches.[2] The stomach was adherent to the liver, and at the seat of adhesion on its anterior wall there was an irregular rent of the mucous membrane nearly three-quarters of an inch long by a quarter of an inch wide, and at one end of the rent the peritoneal coat was perforated; the opening was, however, completely closed by adhesion to the liver. There was no evidence of extravasation of blood or of the contents of the stomach having taken place, and all the injured parts were well glued together. This case is full of interest, although the absence of all or any symptoms which might have suggested the nature of

[1] No. I. was published in THE LANCET of Nov. 2nd, 1895.

Digitized by Google

the injuries which had been sustained was very remarkable. That the ribs were extensively fractured by the squeeze was but natural, and that the convex surface of the liver was ruptured by the same force was also what might have been expected; but that there should have been a laceration of the stomach without symptoms is difficult to explain, unless this fact is made intelligible by supposing that the original rupture of the stomach brought about by the squeezing force had been incomplete and had not extended sufficiently far through all its coats to allow of extravasation. Under these circumstances the progress of the case seems explicable. Had the chest mischief been less severe I am disposed to think that a complete recovery might have been secured to both the hepatic and stomach mischief.

With respect, therefore, to the diagnosis of rupture of the liver, it must be confessed that there are no special symptoms which can be accepted as being indicative of its existence, although severe shock and collapse as immediate results of a forcible local injury to the right side of the abdomen or to the lower part of the right side of the thorax should always suggest its probable existence; and even when the same kind of injury to the same regions is unattended by any such serious symptoms as have been just alluded to, the surgeon should be alive to the possibility of a limited rupture of the liver being present, and he should treat the case accordingly. The cases quoted afford ample evidence to support the truth of this proposition, and are more than enough to support a diagnosis which includes a possibility of serious mischief to the liver in spite of an absence of serious general symptoms when the nature of the injury has been such as to render it probable that such an injury may have been sustained. Had such a possibility been a prominent thought in the minds of those who had the treatment of the cases I have quoted I am tempted to believe that the cases themselves would not have been in my possession, since a recovery might have been secured in the majority of them.

With respect to the diagnosis of rupture of the spleen the remarks which I have just made with reference to the liver are equally applicable. It is to be recognised that cases of limited rupture of this organ, as of the liver, are quite reparable, as illustrated by Preparation 2018 in the Guy's Hospital museum, taken from a body seven days after the injury, and that when such cases recover they, during life, have most probably been regarded as examples of local traumatic peritonitis. In Case 3, already quoted, there was no suspicion of such a form of injury being present, and it was not till a fatal termination of the case by an acute peritonitis that an opportunity of finding out its cause was afforded to the surgeon. When a severe laceration of the spleen has taken place death from shock and collapse due to hæmorrhage is the common result. When the laceration is limited the case may be overlooked and regarded as one of peritonitis. The cautious surgeon should, however, in all cases of injury from any local force applied to the left hypochondriac or lower thoracic region, whether with or without general symptoms, have the possibility of its presence before his mind, and this possibility, however remote, should always lead him to treat his patient with all the care and precaution as if, indeed, he felt sure that this kind of injury existed. The observance of such care, under all circumstances, must be beneficial, its non-observance may be fatal.

Rupture of the stomach when complete is a very fatal injury, shock and irrecoverable collapse, as a rule, speedily following the escape of its contents into the abdominal cavity. When incomplete—that is, when only its mucous lining or peritoneal covering, with or without its muscular coat, is involved—recovery is not impossible. When the external injuring force is applied to the fully distended stomach a rupture is more likely to take place than when it is empty, and this rupture may be either complete or incomplete. In the last case reported (Case 12) it is reasonable to believe that the rupture had been incomplete and had not extended sufficiently far to allow of extravasation of its contents to take place, for no blood was vomited although the stomach rejected food, and there were no primary symptoms to indicate any injury to the organ. In the Guy's Hospital museum there is a preparation (No. 592) showing a laceration and detachment of the mucous membrane of a stomach over an area of about two inches, extending transversely around the middle of the organ to within an inch on either side of the greater curvature. It was taken from a boy aged nine who had been run over by an omnibus and who shortly after admission vomited a blood-stained fluid and died the next day; in addition to the stomach injury, there were found laceration of the liver, extravasated blood behind the pancreas, and a broken thigh. There is likewise a second preparation (No. 594) showing two extensive lacerations in the peritoneal and muscular coats of the stomach, and a very slight tear in the mucous membrane. It was taken from a man who was brought into the hospital dead, having fallen thirty feet on to the deck of a vessel.

That the incomplete separation and laceration of the mucous coat of a stomach, as revealed by the specimen at Guy's Hospital, are clearly possible is an important fact, and I have good reason to believe that the same accident may occur to the intestines and even bladder, and that persistent or intermittent hæmorrhage from either of these organs following injury should suggest its presence. Thus, a man aged thirty-nine fell thirty-five feet upon his abdomen and subsequently passed blood mixed with his motions for seven consecutive days, associated with local tenderness over the colon, and then recovered. I suspected laceration of the mucous membrane of his colon, and upon such a diagnosis treated him successfully. And in a boy about fourteen years of age, who fell from a height upon his perineum and subsequently had hæmaturia and passed fresh clots and pure blood with his urine for some days, accompanied with pain, when there were no indications of urethral or renal mischief, the same diagnosis was rendered probable. At any rate, of this I am sure, that whenever, as a result of an abdominal injury, blood is found to be mixed with the vomit and vomiting recurs in small quantities at intervals, the probability of this symptom being due to a rupture of the mucous lining of the stomach should be entertained and the treatment of the case modified by this opinion.

Grosvenor-street, W.

SPORADIC GOITRE: ITS VARIETIES, AND THE RESULTS OF MODERN TREATMENT.

By GORDON HOLMES, M.D.,

PHYSICIAN TO THE MUNICIPAL THROAT AND EAR INFIRMARY, LONDON.

History.—We may assume that goitre was known objectively in the earliest periods of medical science, although there are no definite allusions to the affection in th Hippocratic writings. In the first century the Alpine goitre were familiar objects in the public eye, as even a non-medical writer, Juvenal,[1] exclaims by way of popular illustration:—

"Quis tumidum guttur miratur in Alpibus?"

Before the third century the Greeks had devised the words[2] "bronchocele" and "tracheocele" to designate such tumours, but nevertheless without understanding anything of the special character of enlargements of the thyroid gland. To their view, in fact, goitre was differentiated by position only from scrofulous swellings of the cervical glands.[3] This confusion existed even until quite modern times, whence the term "struma" is still used for goitre in German nomenclature. The first essay, indeed, to segregate bronchocele from other tumours of the neck does not come to us till 1610, when Riolan[4] demonstrated that a sharp line of distinction should be drawn and goitre relegated to a class apart. Other writers followed his lead until the question was definitely settled. With respect to goitre accompanied by exophthalmos, &c., the general recognition of this malady is almost of contemporary date. The disease, however, was observed clinically and adequately described long before the time of the men whose names are so intimately connected with it. In 1786 Caleb H. Parry of Bath noticed a case of exophthalmic goitre and subsequently many others; but, though a copious writer, his observations in this department only came to light in a posthumous work[5] published in 1825. Parry's experiences, however, were ignored by, or never gained the attention of,

the profession at large. In 1835 Graves of Dublin began to give demonstrations of exophthalmic goitre, and his prominent position as a clinical teacher at once brought the disease into general notice. He was, presumably, unacquainted with Parry's work in the same field. Yet Graves published nothing on the subject till 1843, when he included an essay on the malady in his "Clinical Medicine."[6] In the meantime (in 1840) Basedow of Merseburg brought out a monograph[7] on this form of goitre, which at once attracted notice in Germany. Subsequently exophthalmic goitre has been commonly called "Basedow's disease" by the Germans, but has been better known as "Graves' disease" in other countries. The same credit seems to be due to both men as clinical observers, their originality never having been questioned, but the considerable priority of Parry's observations is altogether beyond dispute.

Semeiology.—In a London throat clinic goitre is met with in three almost sharply defined manifestations. 1. Tumours variable in size, but never very large, variable also in consistency, and apparently of purely local significance. The swelling is not usually remarkable for its symmetrical outline; it may extend across the whole front of the neck or exist only on one side or in the middle. When the whole thyroid gland is involved one lobe may be implicated much less than the other; the isthmus may be the chief seat of enlargement or may appear as a well-defined depression between two lateral eminences. As a rule, the goitre is firm but compressible and more or less movable on the neck. In a minority of cases, however, it is remarkably dense. Some hard goitres have a very regular surface, whilst others are more or less irregular and may even give the impression of a rather rough stone wrapped in a covering of integument. 2. The second class of goitres is comparatively rare; it resembles the first class in seeming to be a purely local manifestation, but the tumour differs considerably as to shape and density. Regularity of outline, smoothness of surface, and concentricity are the rule. Occasionally, however, two or more swellings, conjoined to a greater or lesser extent, are met with. To palpation these goitres give a tolerably clear impression of containing fluid, and are, in fact, cysts. 3. In this division are to be reckoned a number of thyroid tumours, as a rule soft and puffy, and also diffuse and symmetrical, which generally commence in young people between the ages of about fifteen and twenty years. They differ from the two first classes in being allied, in a great majority of instances, to one or more of certain other symptoms—viz., nervous exaltation, neurasthenia, cardiac excitement, anæmia, and less frequently protrusion of the eyeballs (exophthalmos). Some of these, however, are probably merely examples belonging to the two former varieties in an initial stage. In the most pronounced cases the action of the heart is very tumultuous and the pulse may attain 140 or 150 beats per minute. Under these circumstances throbbing of the carotids may be so great as to produce a visible rhythmic movement of the goitre and to communicate a considerable systolic jerk to the hand if placed on the tumour. A murmur may be heard with a stethoscope. Whether there is a pulsation, an expansile movement in the substance of the swelling, is a doubtful point. Looking to the great vascularity of the thyroid body, which receives more blood than the brain, it might well be so, especially if the vessels were dilated or multiplied in proportion to the mass of the goitre. Another peculiarity of this kind of bronchocele is that a variation in size, perhaps at different periods of the same day, is liable to occur. It may happen that the tumour as a regular occurrence is larger in the evening, or the increase may be only occasional, concomitantly with indisposition, mental excitement, or the catamenial flow. As to the exophthalmos, it may be so slight as almost to escape notice, or may proceed to such an extent that the strain on the envelopes of the eye produces ulceration of the cornea. This, however, is rare, and I have not myself met with such a case. The patients when seen by the practitioner are generally in a very nervous condition, sometimes scarcely able to speak intelligibly from muscular tremor and paresis. Tremor and drooping of the eyelids are often noticeable. Anæmia is not constantly present, and occasionally the patient seems to be rather plethoric than otherwise. The evolution of symptoms in Graves' disease seems to take the following order: neurosis, cardiac excitement, goitre, and exophthalmos. It the thyroid gland may, of course, be in a morbid condition before its hypertrophy becomes apparent. All kinds of goitre may give rise to troublesome symptoms by pressing on the adjacent parts of the neck. The most common occurrence is dyspnœa from compression of the trachea, but it may also have neuralgia or aphonia from nerve pressure, giddiness or vertigo from vascular disturbance, &c. When the windpipe is borne on by the tumour noisy respiration—i.e. "roaring"—may occasionally be observed. Such tracheal compression probably occurs only when the growth insinuates itself between the air tube and the sternum. An irksome feeling in the throat or stiffness in swallowing is not infrequently complained of. It is, however, altogether exceptional for a bronchocele to produce any decided subjective phenomena by its mechanical effect on contiguous parts. It may be mentioned that "metastatic goitres"—that is, tumours in various parts of the body having the anatomical characters of the thyroid gland—are sometimes met with.

Pathogenesis.—Despite the persevering researches as to the etiology of goitre, and the immense literature which has accumulated around this disease, its immediate causation remains quite unknown. It is a matter of common knowledge that in certain mountainous districts all over the world goitre is an endemic affection. Popularly the water of the locality has always been accused of generating the swelling, but chemical analysis has not fixed on any substance which can be proved to have a goitre-producing faculty. Some observers, indeed, have abandoned the water theory and promulgated the hypothesis of a "goitre miasma." It seems certain, however, that goitre is a water-carried and not an air-borne disease, but no forecast can yet be made as to whether the honour of discovering the actual *materies morbi* will fall to the chemist or the biologist. To decide between mineral and microbe remains a crux to be solved by some future investigator.[9] It is a well-ascertained fact that "acute" goitre may occur in endemic districts, as when persons inhabiting other parts shift their residence to such places.[10] Families and bodies of soldiers have been thus affected suddenly and as promptly cured by removal. "Goitre wells" are also said to be known in Germany.[11] Some of the goitres arising about puberty and in connexion with pregnancy develop so rapidly as to deserve the name of acute. Considerable collateral advances have, however, been made in this field by the investigations of Ord and others which show that myxœdema results from functional aberrance of the thyroid gland, and cachexia strumipriva from its deprivation—phases of the same pathological condition with different causation. Nor is cretinism, which is esteemed to be a further or hereditary stage of goitre, any longer supposed to result from calcareous deposits (aqueous) about the base of the skull impeding the flow of blood to the brain. It is now known to be the full manifestation of myxœdema when occurring in early life through congenital or artificial loss of the thyroid gland. Experiments have also shown that an apparent bronchocele can be produced in animals by feeding them with thyroid gland substance or extract, a valuable therapeutic discovery, though not enlightening us as to the origin of clinical goitre. We are also not so much in the dark with respect to exophthalmic goitre, although the advance is more in the nature of casting off from old beliefs than of anchoring fast to new ones. The etiological connexion between uterine derangements and this malady, urged by Graves, may now be put aside, considering that the train of symptoms are occasionally met with fully developed in the male sex. Besides, it is obvious that any serious disease occurring in females is almost certain to create a disturbance of the sexual functions. We no longer with Kœlen[12] and his school, look to the sympathetic system as the starting-point of the neurosis, but to the goitre itself.

[9] Among those who have recently given their attention to this subject Kocher of Berne states that a micro-organism found in the water is the actual cause of goitre. He has produced the disease by practising injections on rabbits, &c. (Statistics of Goitre, &c., Berne, 1889.) On the other hand, Berry decides in favour of a mineral origin. (Brit. Med. Jour., June 13th, 1891.)

Digitized by Google

If the symptoms arose from a primary nerve lesion it is evident that we should as a rule have one side only affected, with exophthalmia and goitre confined to that side. No case, however, of unilateral Graves' disease is on record. The thyroid gland, being in a morbid state, may allow some deleterious matter to remain in the blood or may contaminate it by pouring out some perverted secretion. Noting the symptoms arising from an overdose of thyroid gland, Greenfield [14] thinks the affection may represent the converse of myxœdema. But whether the tumour in these cases has a similar extrinsic origin to that of ordinary goitres is still altogether undetermined. Certain predisposing causes of goitre are very well marked, and at the head of these stands sex. Comparatively few cases of sporadic goitre are found in males, though it is said that the endemic form attacks both sexes alike. Next in order comes puberty or adolescence, when most goitres seem to manifest themselves; and further we have heredity, pregnancy, and the puerperal state. I have not met with evidence of heredity, which probably only becomes a factor in endemic districts. Exophthalmic goitre is sometimes met with in members of the same family, and several cases of sisters being so affected have been reported.[15] I have myself seen an instance of two sisters exhibiting the disease under circumstances which suggested a family predisposition.[16]

Pathological anatomy.—The thyroid gland consists of vesicles connected by areolar tissue, and it is larger in females than in males. In case of enlargement the necropsy may reveal a true hypertrophy in which the tumour throughout resembles the normal gland, or the increase may be confined to the parenchymatous elements, which have multiplied and become condensed, in some cases to such an extent as to extinguish more or less completely the function of the organ. In other instances one or more vesicles may have become dilated, afterwards coalescing to form large cysts, which still contain the yellowish fluid constituting their normal contents. If both processes advance together *pari passu* the goitre will consist of a number of cysts about the size of a filbert, more or less, with very thick walls. A veritable fibro-cystic tumour is thus formed, which sometimes attains to great dimensions. Sporadic goitre, however, rarely grows to be very large. In the hardest bronchoceles calcareous laminæ or granules may be found embedded in the substance; or we may have some tumour, fibroma, atheroma, &c. developed from a nucleus in the thyroid body.[17] A few necropsies have been obtained in cases of epidemic (acute) goitre. Here the condition is one of increased vascularity and fibrous hypertrophy. Small cysts may be formed, and the epithelium of the vesicles is infiltrated with granulations.[18] The structural distinction between exophthalmic goitres and those of purely local significance is believed in by most writers on the subject. So far, however, nothing has been formulated. Necropsies have not revealed the development of any "spongy erectile tissue," the existence of which has been imagined by some observers in order to explain the pulsatory impulse and variability of size. According to Shingleton Smith[19] the gland is in a state of "villous and vascular hypertrophy," but Greenfield[20] denies the vascularity; he thinks it, in fact, less than normal. In the view of this, the latest, observer, the thyroid is in a condition of rapid glandular evolution, seen in nothing else but the development of an adenoma. On the whole, perhaps, the appearances are not different from those to be seen in any actively growing goitre. Such patients soon apply to the practitioner, and the disease, if it terminates fatally, runs a comparatively short course. Thus necropsies are likely to be obtained in an early stage of the thyroid growth. Very hard goitres and cysts proper do not appear to be pathologically connected with Graves' disease. Traube and Recklinghausen,[21] however, speak of sclerotic and cirrhotic conditions being found. Semon[22] also states that every form of bronchocele may be met with in conjunction with exophthalmos. The associations, under such circumstances, may be deemed fortuitous. Morbid changes are usually found in the sympathetic nerves, but by no means always, swelling and hypertrophy of ganglia, and degeneration of ganglionic cells. Disease of the central nervous system also exists, and perhaps invariably, but the alterations have not yet been tracked out. Germain See,[23] in fact, considers that the phenomena spring from paralysis of the pneumogastric, and Filehne[24] has even shown that section of the restiform bodies in their anterior fourth produces symptoms in rabbits, &c., very suggestive of Graves' disease. It is a rather curious fact that the cause of exophthalmos has not yet been elucidated satisfactorily by any post-mortem researches. Certain lesions have often been found, such as hyperæmia and extravasation in the retina and choroid, adipose deposit in the cellular tissue of the orbit, &c., but such manifestations do not explain the protrusion of the eyeballs. This phenomenon must, therefore, be the result of transitory conditions, probably vascular engorgement, with more or less serous effusion, and tonic muscular spasms, which disappear with life. In long-standing cases every variety of organic heart disease has been found.

Diagnosis.—Some writers seem to include every tumour of the thyroid gland under the name of goitre. Thus, even cancer of the organ may be denominated malignant goitre. As a rule, however, we understand by goitre, or bronchocele, only those tumours of specific though unknown origin which I have been dealing with in the present paper. The general diagnostic sign of enlargement of the thyroid gland is that the tumour follows the upward movement of the larynx in deglutition. Too much importance should not, however, be attached to this point, as, owing to weight, connexions, loose pedunculation, &c., the motion may not be very perceptible. As goitres are common and tumours of the vicinity likely to be mistaken for them are altogether rare, mistakes cannot often occur, nor are they likely to be of much moment considering that the identical treatment may be the best in each case. It is advisable, however, to distinguish bronchocele as soon as possible from simple inflammation, cancer, hydatids, and gaseous tumours. Thyroiditis comes on more or less suddenly and with the usual accompaniments of inflammation—viz., local heat, pain, tenderness, and concomitant fever. Its early subsidence soon abridges any doubts that may be entertained, but a chronic enlargement may result and pass for a genuine goitre. As to cancer,[25] it is not likely to be diagnosed until it reveals itself by pain or tendency to ulceration &c., or until its nature is proved at the necropsy. Hydatids[26] may be mistaken for cystic goitre, but are usually recognisable as lodgments in the gland as distinct from any general hypertrophy. An air tumour or emphysema may be developed in or about the thyroid body in connexion with a tracheal leakage or fistula. Diagnosis is easy if it can be emptied by pressure and palpation. In any case it conveys a peculiar sensation to the touch. Tumours arising in other parts of the neck—such as enlarged glands, lipomata, &c.—do not simulate goitre and are not likely to be mistaken for it. Small bursal tumours attached to the larynx close to the thyroid gland, and rising in the act of swallowing, are easily distinguished from bronchocele. They rarely grow larger than a pigeon's egg.

Prognosis.—The usual course of a goitre is one of slow increase for an indefinite period, but after three or four years the growth of the tumour is, as a rule, almost imperceptible. Very hard goitres, whatever their age when first seen by the practitioner, may in general be safely predicted to have attained their utmost dimensions. Intercurrent symptoms of any moment are not to be apprehended, unless when actually present in an incipient stage. In Graves' disease the prognosis is more serious, as a certain proportion of these patients pass into a state of hopeless anæmia and

[16] A married lady aged thirty-eight presented herself with rather mild symptoms of Graves' disease. After about a twelvemonth she was well enough to leave off treatment. Five years after her first coming she returned with a sister aged fifty, also married, suffering in the same way. She herself appeared to be practically well. In the second case the action of the heart was very tumultuous; indeed, that was the only marked symptom. In both instances the goitre was small and the exophthalmia but slight. The elder sister was under observation for about eighteen months and expressed herself as being much better. The cardiac excitement had not appreciably abated. These sisters had lived apart in different districts for twelve or fifteen years.

feebleness, and finally perish, usually when attacked by some trifling malady, such as febricula from taking cold &c. Nevertheless, a small percentage of cases seem to be of a temporary nature, pass through a period of exacerbation and decline, and ultimately undergo a practically spontaneous cure. Under these circumstances the goitre may almost disappear under the influence of a kind of cirrhosis. In all instances some dregs of the disease are left. Progressive exophthalmos is, in my opinion, the most unfavourable symptom. It is, indeed, surprising what an amount of cardiac tumult may exist for months, and even years, without giving any great discomfort to the sufferer, provided that in other respects the malady is not signally developed. The menopause is very unfavourable to victims of the disease, but the prospects are worst in the case of young women who have been in delicate health previously to being attacked.

Treatment.—1. In ordinary cases of goitre, such as I have included in the first class, excision of the tumour has been a favourite operation with German surgeons, notably Lücke, Billroth, and Kocher. During the recent Surgical Congress at Berlin the last-named presented his list of such operations completed to the number of 1000. Generally speaking, however, this means of radical cure has rather declined of late years owing to the discovery of myxœdema. This affection was independently noticed by Kocher in the form of "cachexia strumipriva," the term he applied to a train of symptoms observed by him to follow frequently on the total removal of a goitre. Tetany also very commonly occurs after complete excision. The difficulty is now met by leaving a small portion of the gland to fulfil the functions of the organ. Out of the 1000 cases of excision Kocher has put on record, only 12 per cent. of deaths resulted from the operation. A brief allusion will here suffice to the method of treatment employed extensively in India by a Captain Cunningham,[27] and said to have been successful in some scores of thousands of cases. I allude to applying an ointment of biniodide of mercury to the surface of the goitre and then causing the patient to keep the part exposed to the glare of the sun for an hour or several hours until blistering occurs; then the ointment may be reapplied and the case left alone for a twelvemonth, when, if the cure is not complete, the measure can be repeated. This treatment doubtless falls in easily with the habits of natives of the tropics, but it has failed here owing probably to its being less consonant with the routine or perhaps the solar opportunities of European life. We now come to the means of treating goitre introduced about a quarter of a century ago by Alfred Luton[28] of Rheims—viz., the injection of iodine into the substance of the tumour. This is undoubtedly the greatest advance ever made for the relief of bronchocele. Compared with excision the procedure is without risk either with respect to life or myxœdema, whilst in suitable cases the result is almost as certain as in the grave operation. It must be borne in mind, however, that very hard goitres will not yield to this treatment—the success of the injections is, in fact, precisely in an inverse ratio to the amount of induration. Thus, in some instances only a slight diminution of the swelling can be attained, but in a majority absorption will proceed until practically nothing is left of the tumour. I have found that in ordinary cases (when the goitre is, let us say, somewhat less in size than the average fist) an injection of about twenty minims of tincture of iodine once a week produces the maximum of reducive effect. Frequent injections are not, however, necessary to recovery, as the contractile result of a single operation does not die out altogether until a month or more has elapsed. Occasional injections may, therefore, be quite as successful as when they are carried out regularly once a week; but of course the time occupied will be proportionately longer. The slower treatment is advisable in the case of nervous and delicate patients, as the first effect of an injection is to produce some parenchymatous swelling and inflammation, which for two or three days is often accompanied by rather severe pain about the neck. Hence weakly persons soon begin to dread the little operation. In such cases it is well on each occasion to freeze the surface with ether spray at the point chosen for inserting the needle. How the injection acts is not quite certain; but it seems that the point of lodgment forms a focus from which the substance of the gland becomes devitalised in a diminishing degree throughout a considerable area. Consequently an active absorption of débris is set up, stimulated by the inflammation, the iodine, or both. The specific part played by the iodine is, however, a minor one, as good results can be obtained by the similar use of other fluids, such as solution of perchloride of iron, alcohol, dilute acetic acid, &c. As to the mode of procedure, the point of the needle should first be steadied on the spot selected for entry. Then by a quick movement the needle is driven straight in for half an inch, an inch, or more, according to the size of the goitre. Practising the insertion rapidly in this way the stab is so little felt that an ordinary patient will scarcely wince. When carelessly done the needle may carry the skin over the smooth surface of the goitre and enter at an acute angle, being itself bent or broken in the process. It is advisable that the needles for these injections should be stouter than those furnished for ordinary hypodermic use, in which it is only necessary to penetrate to the subcutaneous tissue. Unless the tumour is distinctly bi-lobed or extends across the whole front of the neck, it makes not much difference whether the injections are made always at the same spot or in various places. In the smaller goitres the needle must be directed from the point of entry towards the centre, and thus the site of lodgment will be always practically the same. The effect of the injections is, however, somewhat widespread, and even when the whole mass of the thyroid gland is involved the swelling may be observed to diminish on one side while the treatment is confined to the other side. As to very large goitres in which the enlargement approaches the size of the head or thereabouts, I have only seen one such case. In that the injections were unsuccessful, although the tumour was rather soft and appeared to consist of a number of fibrocysts, each being somewhat larger than a walnut. Such developments are undoubtedly very rare in sporadic instances. The treatment of bronchocele by the internal administration of drugs has been very extensively attempted, but the results are only occasionally satisfactory. Iodide of potassium has of course been generally the sheet-anchor, but hydriodic acid[29] and hydrofluoric acid[30] have, for a time at least, been strongly advocated. At the German Congress above-mentioned Kocher spoke very highly of thyroid gland and phosphate of potassium used conjointly, and such a recommendation coming from a surgeon so habituated to the use of the knife in these cases should certainly carry great weight. 2. In cystic goitres the indications for treatment are simple and after the old-established measures adopted for the radical cure of hydrocele—tap the cyst and inject some fluid capable of setting up an inflammatory process by which the secreting membrane lining the cavity may be destroyed. Thus the tumour is entered about its lower third by a medium-sized trocar and cannula, care being taken to avoid any vein which may appear near the surface. When the contents are evacuated two or three drachms of solution of perchloride of iron (two drachms to an ounce) are injected through the cannula, which is stopped with a plug and allowed to remain in, its retention being ensured by some suitable fixing. The discharge-pipe of the syringe used should be bent at an obtuse angle, so that the body of the syringe is held somewhat upright when injecting. This form was adopted by Mackenzie after he had had a death from injecting air into a vein, in order to ensure that no bubble of air should remain in the liquid injected. After two or three days the plug is removed, when, in the most favourable cases, the discharge will be found scanty, mixed with some pus, and perhaps a little blood. The plug is reinserted and removed daily or on alternate days for two or three weeks until the discharge diminishes to a small amount of purulent liquid. Finally the cannula is withdrawn and the opening is afterwards kept open by any simple device, such as keeping a piece of thin wax bougie strapped into it with plaster, until the discharge ceases and the cyst is evidently obliterated. Sometimes it happens that the goitre refills very rapidly and there is little evidence of the interior irritation which should result from the injection. The latter must then be repeated. In the most obstinate cases Woakes's[31] plan of passing a probe or "acid-carrier" dipped in saturated solution of chromic acid into the cyst may be tried. It must be impressed on the mind of any practitioner without experience of this treatment that the operation,

simple as it is, causes a great deal of constitutional disturbance. In women not particularly robust the pulse will often rise to 120 or more immediately after the tapping, and several weeks will often elapse before the vascular fervescence at length gradually subsides. Deaths have even been reported, though none happily have come under my own cognisance. Females, however, who are in any way fundamentally delicate often remain in a state of weak health for many months. I have never heard of any drugs being vaunted for the cure of cystic goitre, but electrolysis has been tried, as it has in other goitres, with, however, more promising results. According to Dickson[32] of Toronto the best method is to empty the cyst by means of an aspirating needle isolated to within an inch of its point. Then refill the cavity with a solution of common salt and connect the needle with the negative pole of the battery, the positive electrode being applied between the shoulders. A current of thirty milliampères may be employed for fifteen or twenty minutes, after which the sac is to be emptied and the opening sealed. The repetition of this procedure two or three times at short intervals may effect a cure. It may be mentioned that operating surgeons sometimes enucleate the cyst in this class of goitres. 3. Until recent years exophthalmic goitre has been regarded as entirely outside the domain of surgery. The patient, has, therefore, been subjected only to the influence of such drugs as seemed likely to combat the symptoms, especially bromides, digitalis, strophanthus, &c., with perhaps a surface application of electricity to the tumour or to the cervical sympathetic after the manner of Eulenburg.[33] Iodine has not been relied on in this affection as it has in ordinary goitres, although in one case recounted by Trousseau[34] it appeared to have a specific action. Both thyroid and thymus gland, antagonistic substances as it is thought, have recently been administered, but the evidence does not yet enable us to decide as to their value. The persevering use of galvanism to the goitre sometimes produces a diminution of size, but the value of electricity is most marked when the negative electrode is applied to the course of the sympathetic nerve in the neck.[35] An almost immediate reduction of the pulse to 80 or 90 often follows with a general sense of relief to the patient, which may last for two or three days. When there is a tendency to spontaneous cure, or the malady is stationary, such measures are palliative in a very high degree. As early as 1873 Watson[36] of Edinburgh had excised the goitre in three cases with encouraging results, but he was practically without imitators. Now, however, owing to the different views spreading as to the nature of Graves' disease radical measures are steadily coming into vogue. Thus, at the recent German Surgical Congress Mickulicz of Breslau brought forward a number of cases treated by partial excision and also some by ligature of the afferent arteries. Unfortunately, at present the wave of psycho-therapeutics has risen to such a height that a considerable number of practitioners are ready to attribute every successful result to hypnotic suggestion. It may be said, indeed, that in medicine now measures

> "Of great pith and moment,
> With this regard their currents turn awry
> And lose the name of action."

I have myself been accustomed for some years to inject these cases as in ordinary goitres, though at much longer intervals than when there are no signs of neurosis. Not that I consider there is any special danger to be apprehended from the injection in such patients, but merely that the subjects being as a rule in a very nervous state the mere prick of the needle may drive them into hysterics, make a scene, &c., at the time, and even after some days the practitioner may hear that the patient is still displaying unusual restlessness in the domestic circle. After the injection has been done two or three times, however, this condition of things to a great extent passes off, and the sufferer submits with tolerable equanimity to the operation. It is just in this class of cases that freezing the surface becomes a valuable preparatory measure, and it is highly advisable to have recourse to it. I have little doubt but that in the future the cardinal rule for treatment of exophthalmic goitre will be to first get rid of the bronchocele. Electrolysis has been tried in exophthalmic goitre, but I have met with no laudatory report of its action. I may here append some statistical information relating to 287 instances of all forms of goitre which have passed through my own hands:—

Finsbury-square, E.C.

THE VARIOUS METHODS OF OPERATING ON THE MASTOID PROCESS AND THE INDICATIONS FOR THE SAME.[1]

By ADOLPH BRONNER, M.D.

SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL, AND LARYNGOLOGIST TO THE BRADFORD INFIRMARY.

DISEASES of the mastoid process due to affections of the middle ear are very common, but only a small number of cases are operated on; and even when an operation is performed the anatomy of the parts and the technique of the operation are often so imperfectly understood that the results are not as good as they might be. Every surgeon sees large numbers of cases with extensive disease of the mastoid process in which no operation has been performed until the disease has spread to the brain, or where the operation has been restricted to Wilde's incision or to the use of a gimlet or gouge. In operating we have three important cavities to deal with: the middle ear, the attic, and the mastoid antrum or cells. The attic is separated from the middle ear by fibrous bands and ligaments only, and the attic and mastoid antrum are practically directly continuous. The dangers of operating are not very great if we are thoroughly acquainted with the anatomy and pathology of the parts and have frequently performed the operation on the dead body. They are naturally extremely great and grave, if we restrict our methods of operating to roughly and rudely scraping out the middle ear or perforating the mastoid process with a gimlet or gouge. Some of the dangers are: (1) lesion of the facial nerve or (2) of the external semicircular canal; (3) opening the sigmoid fossa; (4) wounding the lateral sinus or (5) the internal carotid artery; and (6) perforating the tegmen tympani. In some cases the positions of these parts vary to a considerable extent, and we have therefore to operate with great caution. Frequently there is only a very small mastoid antrum and few cells, or we only find a few cells on a level with the attic and above the lateral sinus. This is of great practical importance. The indications for operating, according to Schwartze, are: —1. Acute primary or secondary inflammation of the mastoid process, if the symptoms under treatment do not improve in a few days. It is, of course, often difficult to know exactly

when to operate, but it certainly is safer to err on the right side and operate too soon rather than too late. If there is redness and swelling in the upper and posterior wall of the external meatus, or if the apex of the mastoid process is swollen and painful, we should operate at once. 2. Chronic inflammation of the mastoid process with recurrent attacks of swelling. 3. Fistula over or near the mastoid process. 4. Chronic inflammation of the middle ear without apparent affection of the mastoid process if there are symptoms of retention of pus (pain, fever, &c.) or if there is a cholesteatoma. 5. Persistent neuralgia of the mastoid process. 6. Chronic otorrhœa without symptoms of swelling of the mastoid process or of retention of pus, as soon as we think that the inflammation extends beyond the middle ear. In ordinary practice all cases of otorrhœa would be included which, under proper treatment, do not heal in from six to nine months. In cases where there are slight cerebral symptoms it is always advisable to first operate on the mastoid process before opening the brain cavity. Extensive disease of the bone can give rise to such symptoms as slight optic neuritis, strabismus with diplopia, convulsions, coma, &c. Whether there is not slight meningitis present, which subsides after the mastoid operation, it is difficult to say, but certainly in some cases these well-marked cerebral symptoms disappear after the ordinary mastoid operation.

Schwartze in 1873 was the first to publish a series of cases of operations on the mastoid process, and he described a method of operating which was universally practised from 1873 to 1889.[2] The idea was to open up the mastoid antrum from behind the ear and establish a free communication and drainage between the antrum, the middle ear, and the external meatus. Schwartze strongly recommended the use of the chisel and hammer, and these are now in universal use. The operation as described by Schwartze is well known and can be found in all text-books of otology. The wound and cavity are plugged with iodoform gauze for several weeks and a lead nail or wire is then introduced into the fistula behind the ear and worn as long as possible—sometimes for one or two years. Macewen does not like the chisel and uses a rotatory burr for opening up the antrum. He thinks that with the chisel we may break down or crack any thin layer of bone between the diseased parts and the sigmoid groove or the middle cerebral fossa, or that we may loosen septic thrombi of the small vessels. In operating according to Schwartze's method it was soon found that, although the majority of cases did extremely well, in a certain number the bone did not heal for years in spite of careful after-treatment. Experience proved that the majority of these cases were those in which the attic and surrounding bone had been diseased. In 1889 Küstner[4] recommended that in all cases in which the middle ear is extensively diseased we should not be content with Schwartze's operation, but should also remove the whole of the posterior wall of the osseous external meatus. He passes a drainage-tube through the external meatus and antrum. Bergmann[4] suggests that the posterior and also the upper wall of the external meatus should be removed. He thinks that we should be very careful in syringing, as we may thus readily force pus into healthy tissues or cavities. Lucae[5] makes similar suggestions. Zaufal[6] uses Luer's bone forceps for a similar operation. In 1892 Stacke[7] suggested several important alterations in Schwartze's operation. He removes the outer and lower wall of the attic, the posterior and upper wall of the osseous external meatus, and the outer and lower wall of the mastoid antrum. One large cavity is thus formed out of the external meatus, the middle ear, attic, and antrum. These modifications are of such great practical importance that I may perhaps describe the method of operating in a few words. A long incision is made behind the ear, the cutaneous external meatus is cut through above the drumhead, and the whole is drawn well forward. We thus get a clear view of the diseased parts. The remains of the drumhead and the malleus are removed, and a bent probe is passed into the attic. The outer and lower wall of the attic is then chiselled away. The middle ear and attic now form one cavity. A bent chisel is used. The probe is then passed into the aditus ad antrum, and the upper and outer wall of the external meatus and the outer wall of the antrum are removed with the chisel. We now have one large cavity formed by the external meatus, middle ear, attic, and antrum. The ear is then replaced and the wound sewn together. Schwartze now also performs a similar operation, but he first opens the antrum and then works forward into the attic and middle ear. He does not cut through the whole of the cutaneous external meatus, but only through the posterior half. In the last few years most excellent work has been done in this country by Ballance, Arbuthnot Lane, Urban Pritchard, and especially by Macewen and Victor Horsley. They have, however, chiefly dealt with the methods of operating on such cases in which cerebral complications have developed. Macewen and Horsley have made most valuable suggestions for the after-treatment of mastoid operations. In severe cases they prolong the ordinary incision behind the ear forwards round the top of the auricle, and thus make a large gaping wound which can be easily overlooked and dressed. The wound is not stitched at all, but is allowed to fill up by granulations from below. By this method a recurrence of the disease is rendered practically impossible. I hope that in the interests of otology, Horsley and Macewen will publish their experiences in this method of after-treatment. It seems to me to be of the greatest value, and we shall in future be better able to effect a radical cure and prevent any fresh outbreak of the disease. I have for some time drawn attention to the fact that it is a great and fatal mistake to sew up the greater part of the wound, and thus we should leave a large opening so that we can watch the diseased parts. In bad cases I am now adopting Horsley's method, and make a large incision round the ear and use no stitches. It seems to me to be a great and distinct advance in mastoid operations.

In determining which method of operation we should adopt in the various cases it is of course essential that we are thoroughly acquainted with the anatomy and pathology of this region, so that we may be able to form an opinion as to which parts are affected and how far the disease has spread. In acute cases of mastoid disease the ordinary Schwartze's operation suffices. When there is neuralgia of the mastoid process we make Wilde's incision and then remove part of the cortex of the process. In cases of chronic otorrhœa, when the disease is confined chiefly to the mastoid process, Schwartze's operation gives excellent results. When there are no symptoms of mastoid disease it is best to perform the first part of Stacke's operation. We can then thoroughly explore the middle ear and attic. In most cases we will find that the latter is diseased. We then remove the outer and lower wall of the attic, scrape away the diseased bone, and see if any pus or granulations come from the mastoid cells or antrum. There are frequently some mastoid cells on a level with the attic, which are generally overlooked. In some cases the antrum is extremely small. If we think that the antrum is diseased we finish Stacke's operation. In many cases of chronic otorrhœa the disease is chiefly confined to the attic and to a few surrounding cells. In cases of perforation of Shrapnell's membrane, or disease of the ossicula, we should at once perform the first part of Stacke's operation. Some years ago numerous cases were recorded, chiefly by American writers, in which removal of the ossicula cured the disease of the attic. Milligan[8] has lately also published some cases. My own experience, and also that of others,[9] seems to prove that removal of the ossicula may stop the suppuration for a short time, but that in nearly all cases the disease breaks out again. I therefore now invariably strongly recommend Stacke's operation at once, or at least the first part of it. In cases of extensive cholesteatoma we should perform the whole of Stacke's operation and form one large cavity, which can be carefully watched and any recurrence at once seen. In severe cases it is best to leave a large permanent opening behind the ear.

The facts to which I should like to draw particular attention in this short paper are: (1) that we should not undertake operations on the mastoid process unless we are thoroughly acquainted with the anatomy and pathology of the parts and unless we have frequently operated on the dead body; (2) that in all cases of chronic purulent otitis media which do not yield to the ordinary methods of treatment the attic and mastoid antrum should be carefully examined and, if necessary, operated on; (3) that the use of

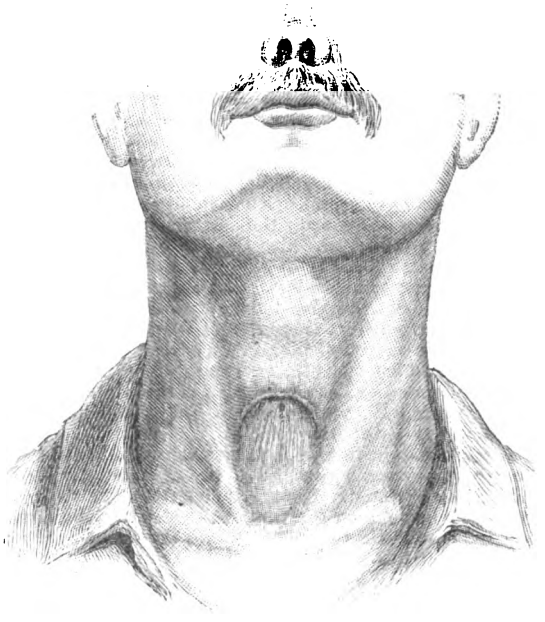
the gimlet or gouge alone is a dangerous and incomplete method of operating; and (4) that in the after-treatment we should not stitch up the wound, but leave a large opening, so that we can carefully watch and treat the diseased parts, and that in severe cases we should prolong the incision well round the ear, plug the wound with gauze, and allow it to heal up from below by granulation.



Bradford, Yorks.

ON A CASE OF MEDIAN CERVICAL FISTULA.

By J. BLAND SUTTON, F.R.C.S. Eng.,
ASSISTANT SURGEON, MIDDLESEX HOSPITAL.

Some months ago Sir Hugh Beevor kindly placed under my care a young adult with a "median cervical fistula." In the lower third of the neck, as represented in Fig. 1, the skin presented what looked like a depressed and puckered scar. At the upper part of this bay or recess there was a rounded opening from which clear mucus exuded. An ordinary probe introduced into this hole easily passed upwards in the middle line directly beneath the skin to stop at the middle of the lower border of the basi-hyal. It was

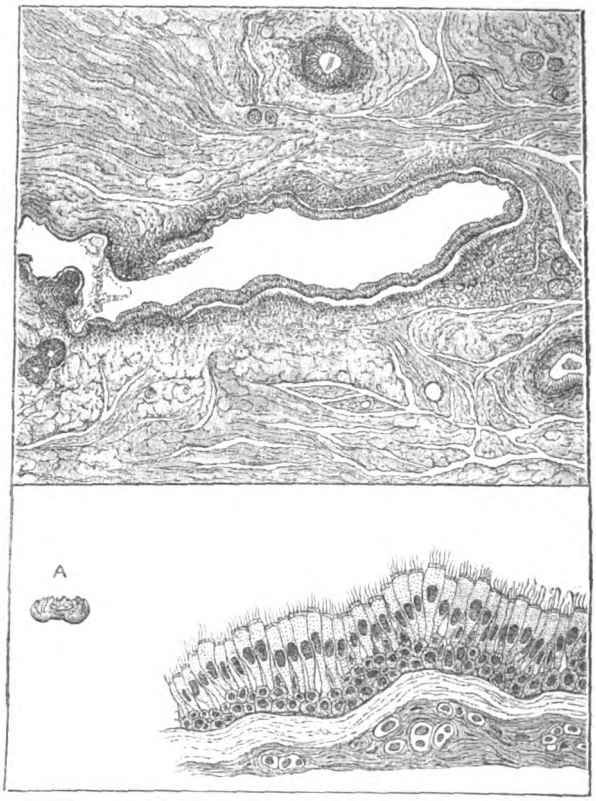


Fig. 1.

Median cervical fistula.

evident that I had before me an example of a persistent thyroid duct. The patient stated that the opening in the neck existed as long as he could remember, but his parents told him that it appeared when he was about three years old. Ordinarily the fistula caused no inconvenience, but during the past two years it seemed subject to catarrh, and the excessive flow of mucus caused him so much inconvenience that he was anxious for relief. The man was admitted into the hospital, and I dissected out the duct. It passed vertically upwards beneath the deep fascia of the neck to the basi-hyal, and in the course of the dissection it was found that near its lower end the duct bifurcated, one arm ending blindly, the other opening on to the skin at the margin of the bay as already described. The upper end of the duct passed behind the basi-hyal, finally becoming incorporated with the thyro-hyoid membrane. I succeeded in removing the duct entire, guided by a probe introduced into it at the beginning of the operation. The incision in the deep fascia was secured by interrupted sutures of cat-gut and the skin brought together by means of fine silk. As no previous attempt had been made to cure this fistula I had the duct carefully hardened and sectioned. Its lumen was lined with typical columnar ciliated epithelium; goblet cells were present. The tissue forming the walls of the duct resembled atrophied thyroid tissue; here and there, as shown in Fig. 2, isolated acini lined with epithelium were detected. This case illustrates very well the chief features of the thyroid segment of the thyro-glossal duct: (1) Its median position and relation to the basi-hyal; and (2) The appearance of the fistula subsequently to birth. It thus stands in striking contrast to branchial fistulæ, which are (1) always lateral and in close relation to the anterior border of the sterno-mastoid muscle; and (2) are always congenital. I have had many opportunities of studying and operating upon these ducts and fistulæ, but this is the first occasion on which I have been able to secure a thyroid duct

Fig. 2.

Section of a persistent thyroid duct.
A represents the duct of natural size. The lowest drawing shows the epithelium more highly magnified.

which had not been damaged by previous attempts at cure, thus the epithelium was in good condition. It is a noteworthy fact that the epithelium of the thyroid duct and persistent branchial fistulæ is identical. This example demonstrates what I have often emphasised—namely, the thyroid duct is a real and tangible structure large enough in adults and even in children to accommodate a probe: it is not a minute passage existing only in the embryo and requiring elaborate histological methods and high powers of the microscope to render it visible.

Queen Anne-street, W.

South-West London Medical Society.—A meeting of this society will be held at 235, Lavender-hill, on Wednesday, Nov. 13th, at 8 P.M. Dr. Chas. W. Chapman will read a paper on Heart Disease in the Young, its Management and Treatment, and proposes, if possible, to show patients illustrating his paper.

In Memoriam.—The honorary medical staff of the Sydney Hospital, New South Wales, intend to erect a tablet in the hospital chapel, in recognition of the great services he rendered to the profession, as a memorial to the late Mr. Louis R. Huxtable, M.B., C.M. Edin., who died at his residence in College-street, Hyde Park, Sydney, on July 30th last.

NOTES OF A CASE OF PRIMARY THROMBOSIS OF THE SUPERIOR LONGITUDINAL SINUS IN AN ADULT, FOLLOWED BY RECOVERY.

BY E. HUGH SNELL, M.D., B.Sc. LOND., D.P.H. CAMB.,
LONDON COUNTY COUNCIL MEDICAL OFFICER TO THE BLACKWALL TUNNEL.

THE occurrence of primary thrombosis in the superior longitudinal sinus in an adult is, I believe, comparatively infrequent; also the symptoms presented are so rarely characteristic that a diagnosis during life appears to be eldom made and not often possible. The following case is probably, therefore, of sufficient interest to atone for its publication.

A young woman, aged twenty-six, came under my care at the Paddington Infirmary on Oct. 27th, 1893, complaining of severe headache together with loss of power in the right arm and right leg; she was unable to walk or stand. The previous history was as follows. Until three weeks previously she had always been in fairly good health; she had had one or two "fits" before menstruation commenced, but none since. She was usually rosy-cheeked, bright, and intelligent. On Oct. 8th she complained of a headache and of not feeling well; this was followed by a severe attack of diarrhœa accompanied by vomiting. She continued to work until the 11th, when she was compelled to remain in bed. No cause for the diarrhœa was discovered. A week afterwards, while still in bed, she complained of more frequent and severe headache situated at the back of the head. The diarrhœa and vomiting still continued; the vomiting was said to have come on after taking food. There was no hæmatemesis. Then, a few days before admission as an in-patient, she complained of weakness in the legs and inability to stand. Mentally she became very dull and stupid. There were no convulsions and there was no loss of consciousness. When seen by me on Oct. 27th her face was flushed, the rest of the body being pale and anæmic. The tongue was pale and tremulous, and covered by some small, dry, brownish patches. She lay in bed in an apparently helpless condition and was very slow and dull in answering questions. She held the right arm rigid and could not move it; the arm could be forcibly flexed without pain to the patient, the only resisting force being muscular. When the arm was held up by a second person it commenced to tremble violently, remaining at the same time rigidly extended at the elbow; the tremors were large and irregular. She could stand with help, but could not move the legs forward; there was some paresis of both legs. The knee-jerks were normal, and there was no ankle-clonus. The plantar reflexes were likewise normal. There was no anæsthesia. It was noticed that the right calf was larger than the left. There was no disease of the heart and lungs. The pulse-rate was 108 per minute, small and irregular. Ophthalmoscopic examination showed that the right fundus oculi was normal, except that the arteries were somewhat tortuous; on the left side the arteries were tortuous and the edge of the disc was slightly blurred; the appearances suggested commencing optic neuritis. The urine was of sp. gr. 1022, acid, contained a faint trace of albumin, with a deposit of urates. At 6.30 P.M. on Oct. 27th she called out to the sister of the ward that she was going to have a fit and said, "Hold me." She then gave a short cry, becoming livid in the face and then unconscious; there was no foaming at the mouth. Convulsive movements commenced in the right arm and right leg, the mouth was drawn to the left side, the eyes were fixed, and the conjunctival reflex was absent; the convulsive movements then affected slightly the left arm and left leg. Consciousness returned in two or three minutes, the patient sobbing. She afterwards explained that she felt that a fit was coming on because of a choking sensation in the throat; she had had no fits before except those mentioned in the previous history. At 6.10 A.M. on the 28th there was another fit of a similar character lasting two or three minutes; it was doubtful when the convulsions began. She knew that a fit was coming on and called out; but it was not attended by screaming. On the 30th an improvement in the mental condition was observed; she could move slightly both the right arm and right leg, but could not walk without assistance. The right grasp was feeble, the left very good. The tongue was still dry, with brown patches. The pulse was 108 and irregular. She was very anæmic and had been constipated since her admission. Ophthalmoscopic examination showed slight, but distinctly commencing, optic neuritis in both eyes. Iron, quinine, and arsenic were administered, as also stimulants and a nourishing diet. On the 31st the mental improvement was still more marked. Œdema was looked for over the scalp and forehead, but none was found. There was no cerebral tenderness. The face was still slightly flushed; the tongue was not so dry and brown. The disproportion between the calves noticed on her admission was still more marked; the circumference of the right calf was 13¼ in., and that of the left 12 in. Deep tenderness existed in the right calf, this not having previously been noted; but there was no tenderness in the popliteal regions or in the femoral veins. The pain in the head was always worse at night time and sleep was very much disturbed. The right grasp, measured by the dynamometer, was 25 and the left 37½. On Nov. 1st the grasps were: right, 23; left, 57. On the 2nd the pain in the head was better, and she passed a better night; the tongue was clean. On the 3rd the grasps were: right, 25; left, 50. During the night of the 4th an erythematous rash appeared on both arms, which caused much irritation; its distribution was confined to the external surface of the arms and the posterior surface of the forearms. It was more marked on the left side and disappeared on pressure. By the 6th the rash had disappeared. On the 8th the optic neuritis in both eyes was found to have much increased; the edges of the discs could not be defined. On the 11th both grasps were 48. On the 16th the right calf measured 12½ in. and the left 12 in. There was no tenderness of the former. The right knee-jerk was less marked than the left. She no longer complained of headache. On the 24th no recurrence of the pain in the head was found to have taken place. The knee-jerks were equal and normal. She could walk without limping, and there was no obvious weakness in either leg. On the 30th ophthalmoscopic examination showed that the neuritis in the right eye had improved, and the edge of the disc could be defined; the improvement in the left eye was not so marked. On Dec. 2nd the right grasp was 60 and the left 70. On the 7th the right calf remained half an inch larger than the left. The optic neuritis had still further diminished; the vision, which had previously been impaired, was improving; there was no weakness of the arms or legs, and she was intellectually very bright. She left at her own request on the 8th, and she did not again come under my observation, but I heard a month later that she felt quite well, and that her vision was unimpaired. The temperature was never above 100° F.

Remarks.—The history of diarrhœa continuing for a fortnight; the subsequent paralysis of the right arm and right leg, with some paresis of the left leg; the fits with convulsions commencing on the paralysed side; the impairment of the intellect; the tremulous tongue; the headache; the optic neuritis; the rigidity and large tremors of the right arm—all these suggested to me that the case was one of so-called "primary" or "marantic" thrombosis of the superior longitudinal sinus blocking the veins from the left hemisphere more than those from the right, and led me to form an unfavourable prognosis, but at the same time induced me to try what result tonics, stimulants, and a good diet might effect. In spite of the absence of any œdema of the scalp or forehead, the subsequently noticed signs of thrombosis in the deep veins of the right leg appeared to support the diagnosis, and the gradual improvement and ultimate recovery seemed to exclude any other alternative. It is possible that the extreme anæmia may have assisted in producing the optic neuritis; but, on the other hand, it may have been wholly due to the thrombosis in the sinus. A perusal of the monograph on Thrombosis of the Cerebral Sinuses by Professor Dusch[1] shows that of 11 cases of distinctly "primary" thrombosis quoted by him 7 occurred in children and aged people, and 4 between the ages of twenty and sixty; 3 only of these latter arose from acute conditions, and were attributed (by Cruveilhier and Schmucker, who originally recorded them) in two cases to too copious venesection and in the third to diarrhœa. It appears to be well established that among young children diarrhœa is by far the most common cause. A necropsy was made in all the cases quoted by Professor Dusch. That the

[1] Translations of the New Sydenham Society, 1861.

Digitized by Google

condition is regarded as especially fatal may be due to the scarcity of those cases in which a diagnosis is possible. The only instance of recovery from such a condition that I have been able to find is one recorded by Voorman and quoted by Dr. Gowers;[2] in this case the patient was a child aged five months, and the recovery was incomplete.

East Greenwich, S.E.

SPASMUS NUTANS.

BY GILBERT A. BANNATYNE, M.D. GLASG.,
HONORARY PHYSICIAN, ROYAL MINERAL WATER HOSPITAL, BATH.

SPASMUS NUTANS, or head-nodding, while comparatively rare in children, is almost unknown in adults. Except the cases mentioned by Dr. McGillivray of Dundee,[1] I have failed to find any mention of it in the literature at my command. Possibly, therefore, the report of such a unique condition may be of interest to some of the readers of THE LANCET. For details of the disease in children I would refer them to Henoch,[2] who was the first to point out the features of the disorder, and to the papers of Dr. Stephen Mackenzie,[3] Dr. Gee,[4] Dr. Hadden,[5] and Dr. G. Dickson.[6]

A man aged forty-three was admitted to the Bath Royal Mineral Water Hospital on Aug. 30th, 1895, suffering from pains in the back and right hip, with lateral spasmodic movements of the head and eyes. According to the report furnished by his medical attendant the patient had suffered from rheumatism and sciatica from about the middle of May and had been steadily getting worse up to the time of admission. He also stated that the patient had suffered from nystagmus from birth. On admission the patient stated that fifteen years previously he had what he thinks was an acute attack of rheumatism; since then he had been free from it until the onset of his present illness. There is no history of syphilis, either inherited or acquired; the family history is good. He complained of pain about the right hip and down the course of the right sciatic nerve, and to a less extent over the lower lumbar spines. His complexion is unusually fair, but he is not an albino. On examining the joints no changes were detected, the movement being free, and on passive movement there was no pain. There was no pain or tenderness down the course of the sciatic nerve, and there was no wasting or other sign of nerve degeneration. Sensation was normal, and the reflexes were active. Over the lumbar spines some slight tenderness was obtained on deep palpation. At the same time, although not complained of, it was noticed that he suffered from horizontal nystagmus of both eyes, with internal strabismus of the right eye and lateral oscillation of the head. On inquiry these symptoms would appear to have existed as long as he could remember and, he believed, from birth or soon after. No cause could be given for its onset, and as far as he knew he never was seen by a medical man. He stated that it had not altered much in degree or character, and had never been sufficient to interfere with his work. His schooling seemed to have been of the scantiest. At times he was troubled with a feeling of weight and heaviness in the head, principally on the right side. For years he had been subject to sudden attacks of partial loss of consciousness. These were unaccompanied by any premonition and usually made him either fall backwards or at least clutch at something to prevent him from falling. He never became quite unconscious and had never hurt himself. The fits at their worst occurred as often as twice or thrice a week. They became worst during the five years from 1888 to 1893, after which they gradually became fewer and have now entirely ceased. The other symptoms have altered little. The movements of both head and eyes became worse when he was excited or when his attention was drawn to them. They ceased during sleep and to a certain extent when lying down—that is to say, whilst in the recumbent position the movements of the head ceased entirely, whilst those of the eyes became slower and not so frequent. On closer examination it was seen that the first movement of both eyes and head was to the left, and the divergence was certainly greater to that side of the middle line than to the right. The movement was entirely of a horizontal nature. The movements of the head and of the eyes did not correspond with each other either in number or in rhythm; the eyes oscillated from 80 to 100 times per minute, whereas the head only did so from 20 to 30 times, or it might be even less if his attention was taken up by other things. He had little control over either movement, the mere fact of trying to control them at times seeming to bring them more into evidence. This became so marked that now and then twitching of the left facial muscles occurred. The strabismus also at those times became more marked. Mr. W. M. Beaumont kindly examined the patient's eyes for me, and he reports that there is "well-marked horizontal nystagmus of both eyes, exaggerated if the eyes are deviated either to the right or left. There are also frequent lateral or slightly rotatory movements of the head not synchronous with the nystagmus and somewhat irregular. He appears to be able to control the movements to a slight extent, and they cease when he lies down. The nystagmus does not cease when he lies down. Interior of the eyes by ophthalmoscopic examination: There is a delicate veil-like opacity of the vitreous, with fine particles floating about. The choroidal vessels are seen very clearly (he is an extremely fair man, with light-yellow hair, but not albinic), and in each eye there are more than twenty dioptres of myopia, with posterior staphyloma. His vision cannot be improved beyond $\frac{6}{6}$. The bad vision and nystagmus are said to be congenital." Treatment consisted in a course of the mineral waters, both externally and internally, with iodide of potassium. On Oct. 10th the patient expressed himself as feeling quite well, being free from all pain and also of the feeling of weight in the head. He stated that he was as well as he had ever been, and, being anxious to return to work, he was discharged. Little or no change occurred during treatment in the head and eye symptoms, and one may safely say that in all probability they will remain for the rest of his life.

Remarks.—Looking at the case as a whole it may, I think, be classed with those to which the somewhat misleading term of "spasmus nutans" has been given. In saying that the name is misleading I mean in so far as it implies that the head is nodded, for in a certain proportion of cases the motion is not from back to front, but from side to side, and, therefore, strictly the term should not be applied. It has been given, however, and has come to be associated with a sufficiently well-marked series of symptoms, and it would be a pity to add confusion by applying a new term to those cases in which the movements are lateral, as has been suggested. The question of diagnosis must remain for the present undecided. I am not inclined to believe that this is only one of the many forms in which epilepsy is manifested, but rather think that it is a disease *per se*. It must be borne in mind that head movements with nystagmus are fairly common in grave nerve disorders merely as symptoms. Whether, when they occur, as in the above case, unaccompanied by other symptoms, they are to be regarded as constituting a regular disorder or only as a group of symptoms having a deeper significance must for the present be left alone. The points of most interest in the symptoms are their persistence, the lateral character of the movements, the attacks of *petit mal*, the facial twitching and strabismus, the fair complexion, and the pain and tenderness over the spine. The outstanding feature is undoubtedly the persistence of the symptoms. In almost all the cases hitherto reported the disease has proved to be transitory, seldom lasting more than a few weeks and ceasing, as a rule, when some reflex exciting cause has been removed. With the exception of three cases described by Henoch[7] and nine mentioned by Dr. McGillivray,[8] all the other cases hitherto reported have been under two years of age and mostly under one at the beginning of the attack. As a rule, it has lasted for from a few days to several months, but with the exception of the cases mentioned never longer. Henoch's three cases were seen respectively at the ages of nine, ten, and twelve. In only one was the onset fixed, which was a year and a half before coming under observation; the other two cases were accompanied by other symptoms pointing to central nerve disease, and therefore cannot be regarded as pure cases. The cases of Dr. McGillivray are of much interest. Eight occurred in one family in four generations, thus establishing a hereditary tendency in the

complaint. It was apparently transmitted by the female side, skipping one or more generations, more often than by the male. The disease was congenital, and in all cases persisted throughout life. The other case occurred associated with three others in which lateral nystagmus only was developed, and it would look as if the nystagmus were an early or not so fully developed condition. In Dr. McGillivray's cases the sight was usually affected. In the case under consideration it is not only seen in an adult, but from the history given it cannot be doubted that it came on early in life and had since persisted without intermittence. It was likewise unaccompanied by any further symptom pointing to other and more grave nervous trouble. Is it to be classed with those of Dr. McGillivray in so far as to call it congenital (no direct evidence exists that it was so), or is it to be classed with those of Henoch and others? There is, on the one hand, no history of heredity, and, on the other, it is a mystery why it should have persisted. Henoch and Dr. Hadden are of opinion that it arises from reflex impulses set up by disordered dentition or other slight irritation in the earlier months of childhood. This patient in all other respects is a strong, healthy man, and has hitherto been quite capable of carrying on his somewhat arduous occupation. The family history affords no clue. He is married and has healthy children, and there is no history of syphilis, either inherited or acquired, and no epilepsy. It must be presumed that it originated in some hitherto unexplained way, but probably in the manner suggested by Henoch. Next in order is the direction of the movements. In the large proportion of cases hitherto reported these have been of a nodding character; in some, however, this character has been modified by a more or less lateral movement, producing a rotatory spasm, and in a smaller proportion there has been a pure lateral movement. The eye movements as a rule correspond in direction with that of the head. In this case the motion was undeniably first to the left, showing that the spasm commenced in the left muscles; but one could not determine whether the corresponding spasm on the right side was only an induced and subsidiary spasm or an independent one. I am inclined to think that probably the right-hand spasm was purely sympathetic. The facial twitching I have not seen mentioned in any other report, and it is probably only a further extension of the disease. It did not occur so frequently and was not so marked as the head spasm, being usually brought on by excitement. The strabismus only occurred during excitement, but apart from the disease the condition of the eyes themselves was sufficient to account for it. What was described as rheumatic pain was, I take it, entirely nervous in origin, there being no joint or other rheumatic phenomena. Henoch states that the disease arises from some reflex irritation such as dentition acting on an unstable nerve system. This belief would appear in the majority of cases to be well founded, as many, if not all, seem to be cured on the removal of the irritating cause. If the disease is looked at as a whole the significance of the attacks of *petit mal* is increased. It points to some lesion on the surface of the brain rather than to one involving the nerve roots. As I have explained, I do not consider the head and eye oscillations to be mere, however rare, symptoms of epilepsy, but rather that they all have a significance in common. In this and similar cases probably what was at first only an instability of the ultimate nerve elements has passed insensibly into actual organic change. In hereditary cases this instability would be all the more marked and slighter exciting causes would bring about the onset. Probably the disease would prove more resistant to treatment and more likely to take on a permanent character. The lesions probably might be localised in the first and second frontal convolutions, as in monkeys. In these animals a centre for the movements of the head and eyes has been found to exist in that locality; the centre for the facial movements lies in the lower third of the ascending frontal, and therefore, if the face be implicated, the lesion, although slight and superficial, must affect a comparatively extensive area. As to the nature of the irritation, although very fair, the patient is not an albino, but it is rather suggestive that in albinism nystagmus is common through the early visual impressions being painful and of disturbing excess through the absence of pigment. Such ideas open up endless vistas of theories, which can in the present state of our knowledge only end in theories. Taking the disease *en masse*, it appears to me to be due originally to some over-action of certain nerve cells, with induced spasms in certain muscles, producing oscillation of the head and eyes, and at times through some sudden discharge of nerve energy giving rise to regular attacks of *petit mal*. The occurrence of the latter symptom is a good guide to what is going on, as it is known that it is due to a sudden liberation of nerve force. Experiment has taught that *petit mal* can be produced by irritating the cells of the cortex and thereby causing over-action of these cells and a sudden discharge of their energy. The probability is that in such cases as have been described there is an initial defect in the cortical cell nutrition, which, being determined by some reflex irritation, passes first into a temporary state of increased activity and, if the irritation be severe enough or be sufficiently long continued, of actual organic change. I hope I have made my views sufficiently clear, and I reiterate that I consider the affection a disease *per se* and not merely a subsidiary form of epilepsy.

Bath.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PHLEGMASIA ALBA DOLENS IN THE VIRGIN.

BY DANIEL MOWAT, M.D. EDIN.

THE case described by Dr. Herman in THE LANCET of Oct. 5th recalls a similar one which occurred in my practice in January last. The patient was eighteen years of age, tall, and slightly anæmic; her menstruation was regular but somewhat scanty; she had no cardiac trouble. She was suddenly seized with pain in the right thigh, shortly after which the leg began to swell. The patient became unable to walk, and the temperature rose. The leg presented the usual appearance of "white swelling." There was no trace of sugar or albumin in the urine. Under treatment the limb began to recover, but it was several weeks before the patient was able to stand. Last September she had a slight return of the phlegmasia in the same leg. Dr. Herman's case is still more interesting as both legs were affected, the one becoming swollen as the other recovered.

Stamford-hill, N.

A CASE OF QUINTUPLETS.

BY J. W. STOKER, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

THE patient was a woman aged thirty-five years, 5 ft. 1 in. in height, of very slight build, and healthy. Her mother had given birth to twins on two occasions; apart from this no further family history has been ascertained. She had been married for six years and had borne four children at full period, and never had any difficulty in labour. Coming to the present case the patient computed that she had been pregnant for six months and said she could not understand why she felt much bigger than on former occasions. She complained of a pain (fixed) in the left side of her abdomen, and imagined that she was larger on the same side. Otherwise she felt well up to two days before her confinement. Labour set in on Sunday, Oct. 20th, at 10 P.M., and was concluded on Monday at 6.45 A.M. On that day the pains were regular, though not strong, and the contractions good. On my arrival at 3 A.M. the patient was strongly in labour, and on making an examination I found the membranes ruptured and a shoulder presenting. There was no difficulty in performing version. The child was dead (recently). On making an examination after the birth of the first child I easily became aware of the existence of more than one remaining fœtus. The membranes protruded and became tense at each pain. The presentation was a transverse one. In this case, also, there was not much difficulty in performing internal version. The child was alive and lived a couple of hours. The third fœtus was also enclosed in a separate bag, which required to be ruptured. This was a breech presentation, and the child was delivered naturally, being alive and surviving for an hour. In the fourth case the same procedure of rupturing the membranes was gone through, and immediately there was hæmorrhage to an alarming extent.

Digitized by Google

so much so that the mother collapsed. I turned as quickly as possible after administering stimulants, but the difficulty did not end here, as the chin became locked in that of the fifth. There were some difficulty and considerable delay in freeing them, though the extent of the locking was not at any time formidable. The child was dead (recently). The fifth was a head presentation and the child was delivered naturally; it was alive and lived for half an hour. The placenta was delivered about five minutes after the birth of the last child and consisted of two portions united by a narrow isthmus. One, the smaller, had two cords attached centrally and close together; the other, and larger, had two cords attached in a similar way to the former, and one where it was joined by the isthmus. It appeared to be perfectly healthy. The cord of the fourth child was so short that it had to be tied in the vagina. The mother rallied quickly and has gone on well. The children were all females and much about the same size, making a total weight of eight pounds, or, on an average, a little over one pound and a half each.

Rainham, Essex.

A PECULIAR CASE OF DISLOCATION OF THE SHOULDER-JOINT.

By C. C. BAXTER-TYRIE, M.B., C.M. EDIN.

THE methods by which a joint may become dislocated are many and various. Especially is this true as regards the shoulder-joint, and the following case, being perhaps unique, seems worthy of being added to the list of peculiar histories of causation. On Sept. 18th I was called to see a patient whom I found suffering from a subcoracoid dislocation of the head of the humerus. On inquiring as to the cause of the injury I elicited the following peculiar history. The man was returning on horseback from the smithy to his house when the horse ran away up a steep hill. The animal after going a few hundred yards abated speed, and the rider, with the intention of "taking it out of the brute," raised his hand to strike. The horse caught sight of the whip and sprang forward, with the result that the man felt an acute pain and a sense of something having given way in his shoulder. He did not fall off, but rode a little further into a farmyard, where he was helped to dismount. Had he been thrown I should have been dubious as to the above history of causation. As the weight of the whip was inconsiderable (four ounces) the explanation of the cause of injury is, I think, found in the inertia of the arm converting it into a lever of the first order. The coraco-acromial arch, instead of fulfilling its normal function of preventing displacement, acted in this case as a fulcrum. The limb from the fingers to that point acted as the "long arm," and the head and part of the neck of the humerus served as the "short arm." The inertia of the arm, left as it were behind, supplied the power, while the ruptured capsular ligament and displacement of the head of the bone would represent the work done.

Victoria-road, Keighley.

NOTES AND OBSERVATIONS ON A CASE OF SUPPOSED DELAYED INHERITED SYPHILIS.

By TOM ROBINSON, M.D. ST. AND.

A MAN aged thirty-six consulted me in January, 1890, for a swollen testicle, which he said had crept slowly and painlessly on. There was an absence of any history of gonorrhœa, injury, or previous attack. On examination the left testicle was found to be as large as a sheep's heart. The epididymis was not involved. The surface of the testicle was smooth and was somewhat pear-shaped. It had that dense, heavy feel which has always been noticed in cases of syphilitic orchitis. A most careful inquiry was made into the history of the case, without discovering any subjective or objective evidence of syphilis, the narrative being free even from evidence of the possibility of contagion. The patient was a married man and the father of four children, all of whom were apparently healthy. His wife was free from any display of syphilis, and she had never miscarried. It was not possible to carry the history of the patient any further back, as his parents had been dead for some years and he was an only child. His childhood had been, so far as he knew, a healthy one, and he certainly betrayed no evidence, so far as physiognomy or teeth were concerned, of having inherited a syphilitic taint. Sir James Paget was good enough to see the case with me, and he corroborated the opinion that it was one of delayed inherited syphilis. The patient was ordered to rub a drachm of blue ointment into the enlarged gland twice a day, and, at the same time, to take a mixture three times a day containing five grains of iodide of potassium in each dose. In six weeks the volume of the testicle had diminished until there was little apparent difference between the two organs.

Experience has already demonstrated the fact that inherited syphilis has three epochs of activity: (*a*) where it manifests itself at or about birth; (*b*) where it manifests itself during childhood; and (*c*) where the disease is delayed until after puberty. Cases such as this one are, I believe, not uncommon. If inherited syphilis will lie dormant for six years, why should not the period be prolonged to thirty-six? We know that in the acquired form of the malady there is no limit to the time in which the organism may not be attacked by the sequelæ. The sequelæ of scarlet fever, measles, and other blood diseases will spread over a number of years, and senile scrofula has become current coin in the medical profession. The interest of all syphilitic problems lies in the attempt to follow backwards the footmarks of the poison. Our difficulties are sometimes insurmountable, but there is no disease which leaves in its path so many evidences of its march and none which possesses a more potent interest.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

A CASE OF TUBERCLE OF THE BLADDER IN A MALE; SUPRA-PUBIC CYSTOTOMY; RECOVERY.

(Under the care of Mr. W. H. BATTLE.)

WE have published this year in THE LANCET other cases of supra-pubic cystotomy for the cure of tubercle of the bladder in the male, and in most of them the results were very satisfactory. It is admitted that in this case a sufficiently long period of time has not elapsed since the patient left the hospital to enable it to be said with certainty that the man is cured, but the prospect is undoubtedly good, and the benefit already received is great. Tuberculous disease of the bladder is one of the most painful of all affections of that viscus, the frequent painful micturition being most distressing, and the patient obtaining but little rest, either day or night, whether in bed or going about. It is not surprising, therefore, that there is now a tendency to attack the disease boldly and directly when examination of the patient makes it probable that the disease is primarily of the bladder and has not extended to other parts. The results already obtained are so satisfactory as recorded that no surgeon can be blamed for refusing to continue week after week medication through the urethra with an uncertain result in cases such as that described, when an incision above the pubes will enable him to exactly gauge the extent of the mischief and arrest its progress by scraping, the bladder being subsequently drained for a few weeks. For the notes of the case we are indebted to Mr. Paterson, dresser.

A tall, strongly built man aged thirty-one was admitted to St. Thomas's Hospital, under the care of Mr. Mackellar, on July 20th, 1895. The family history was good; there was no history of phthisis. He was a married man with two healthy children. There was no illness of moment in the previous history. The first symptom noticed was severe pain in the penis five months before admission, followed by a

Digitized by Google

burning sensation during micturition; the pain was then worst at the beginning of the act. A week later he passed some blood in the urine, bright red in colour, and coming after all the urine had been expelled. He had medical treatment for this, and after getting worse for a time, with shooting pain referred to the rectum and abdomen, recovered to a great extent. About three weeks before admission the blood again appeared in the urine, the pain in the penis and bladder increased, and the urine was noticed to be "thick and mattery," depositing an abundant sediment, sometimes white and sometimes red. He stated that he had lost 2 st. in weight recently. On his admission there was nothing abnormal to be detected in the abdomen, and no fulness in the kidney region. On rectal examination the prostate could just be felt, but there was no definite enlargement. The epididymis was normal on both sides. The heart was healthy; the lungs were emphysematous. The temperature was normal. Micturition took place every hour or hour and a half when he was in bed. The urine was acid, of specific gravity 1012, and contained pus. On microscopical examination pus was present in large quantities, also blood corpuscles. On July 29th, although the patient had been lying in bed, there was more pus in the urine than on his admission. Two examinations for tubercle bacilli were made, with negative results. He had attacks of sharp pain about the "back passage," especially after defecation. There was little improvement under general treatment, and on Aug. 12th Mr. Battle (who was on duty for Mr. Mackellar) examined the patient under ether. The surface of the bladder when the sound was passed appeared to be abnormally rough, but no distinct tumour could be found. This roughness was most marked in the position of the opening of the right ureter. The bladder was also examined with the cysto-cope, but with negative results. He complained of pain for some time afterwards and had a bad night although a morphia suppository of half a grain was administered. Next day the temperature was 101·4° F. On the 14th Mr. Battle performed suprapubic cystotomy. The bladder was washed out with boracic acid lotion, and about three ounces of the solution were left in. The silver catheter was also left in position, and a piece of elastic tubing tied round the penis. The usual median incision was then made, and the bladder wall exposed. A curved needle with silk was passed through the wall of the bladder on each side of the middle line. A median incision was made, and the halves were held apart by the silk sutures. The finger was introduced, and as a velvety condition of the mucous membrane was only felt the bladder was thoroughly examined with the electric light, a Sims's speculum being introduced at the upper angle. The wall of the bladder was thickened; the mucous membrane bled very readily when touched, especially in the neighbourhood of the right ureter, where some roughness could be felt. Yellowish, raised patches could be seen in places, and one long streak about half an inch wide ran down the posterior wall from the aperture. In several places granulation-like projections could be felt. These were scraped away with the finger-nail. As much of the softened tissue as possible was rubbed off with the finger. The shreds and clots were washed away with boracic lotion, and the whole was sponged out. The sides of the wound were stitched to the wound in the abdominal wall (the incision in the bladder having been previously lessened by the insertion of a silk suture), and a drainage-tube was inserted. The abdominal wound was closed in its upper part. Cyanide gauze was used as a dressing. On the 19th a tracheotomy tube of rubber was inserted, and the contents of the bladder, by means of a long tube placed through the tracheotomy tube, were drained into a vessel under the bed. The bladder was washed out daily with boracic acid lotion. The temperature was slightly raised, but was under 100°. During some days preceding the 31st the patient passed some urine by the urethra and had a return of the old shooting pains in the back passage. It was not easy to keep the tube in position. The stitches had been removed some days previously. On Sept. 14th the suprapubic tubes were removed. There was very little urine passed into the dressings, most of it being passed per urethram and without pain. There was still some complaint of pain in defecation. His general condition was good. On the 17th the urine was of specific gravity 1018, slightly alkaline, and contained a little albumin, but much less pus than when last examined. The wound closed towards the end of September, and when the patient went to a convalescent home on Oct. 3rd there was no albumin in the urine or pain in micturition. He could hold the urine for a longer period—viz., for from two to three hours—had become much stronger, and had put on flesh considerably.

Remarks by Mr. BATTLE.—This case was a fairly typical one of tuberculous disease of the mucous membrane of the bladder. It is true that no tubercle bacilli were found in the specimens of urine examined, but it is notoriously difficult to find tubercle bacilli in the urine, and the condition of the bladder was of itself convincing proof of the nature of the disease when it was exposed at the time of operation. It is very probable that in this patient the bladder affection was primary, and not secondary to any disease of the kidneys. Careful examination under an anæsthetic failed to give any evidence of renal enlargement on either side. The patient was a big man, with strong abdominal muscles, so without the use of an anæsthetic it was not possible to speak definitely on this point. Examination of other parts, such as the lungs, prostate, and epididymis, showed no disease. A still more satisfactory proof as to the healthiness of the kidneys was afforded by the condition of the urine when the patient left the hospital at a later date. It also showed the remarkably improved state of the bladder. It is quite evident that no other method of treatment would have been so efficient as the one adopted; the disease was scattered irregularly throughout the bladder, even in the fundus, and could have been but slightly affected by intra-vesical medication. By scraping away all the diseased patches with the finger-nail and then giving prolonged rest to the bladder the best chance of cure was given. In my opinion drainage alone, even when prolonged, is not likely to be so effective, otherwise a better result would have been obtained in times past when the perineal route was used. It is too early, perhaps, to say that the man is cured, but there is no doubt of the great relief which he has obtained. I am much indebted to Mr. Fox-Symons, who was the house surgeon when the man was under treatment, for his attention to the case.

VICTORIA HOSPITAL, HULL.

CASES OF BASAL (SUBARACHNOID) DRAINAGE; REMARKS.

(Under the care of Mr. ALFRED PARKIN.)

WE are pleased to be able to place before our readers notes of two more cases in which drainage of the ventricles has been carried out for hydrocephalus. It is evident that the operation for the insertion of the drain is not one which is either difficult or prolonged, and no physician need hesitate in recommending it for fear that it should be too severe for the child. The drainage should be gradual and continued for some days. The result in the first case was undoubtedly satisfactory. The second teaches a valuable lesson as regards the rate of drainage advisable. The other cases alluded to by Mr. Parkin in his remarks belong to a more unfavourable class for treatment of any kind, and the prognosis, from the fact that in each patient unconsciousness had set in for some hours, was exceptionally bad. Perhaps the physician will be able some day to define more clearly the point in the progress of a tuberculous meningitis when the interference of the surgeon may be requested with a greater possibility of success.

CASE 1.—A male child aged three and a half years was admitted into the Victoria Hospital, Hull, on Feb. 27th, 1894, for fits. The head was large, globular, nineteen inches and a half in circumference, and out of proportion to the rest of the body. The anterior fontanelle was still open, but there was no extension backwards between the parietal bones. The child was said to have had numerous fits since birth, apparently of a general character, and recurring about once or twice a month. There was little sign of intelligence; he was unable to talk or walk, and the bowels and bladder acted involuntarily. No attempt was made to pick up or play with toys. The sight was apparently good, there being no changes in the disc. The condition being obviously one of chronic hydrocephalus, it was determined to drain the subarachnoid cavity in the manner adopted by Mr. Parkin and described in THE LANCET of Nov. 18th, 1893. This was accordingly done on March 17th by removing a small piece of the occipital bone a little to one side of the median line by means of a gouge, enlarging the opening with forceps until it was the size of a sixpenny-piece, incising the dura

Digitized by Google

cnater, and inserting a small silk drain beneath the cerebellum after first passing a curved probe into the cavity of the fourth ventricle so as to open up the post-medullary velum in case the normal openings had become closed for any reason. In this way excellent drainage was established without allowing a too sudden or a too copious discharge of cerebro-spinal fluid. The after-history of the case was marked by a gradual but steady improvement, which has continued up to the present time. The wound healed rapidly; there was no rise of temperature, and the general condition remained excellent. Two days after the operation the knee-jerks, which were previously absent, returned, and the next day attempts were made to take hold of things. A week later the child began to sit up by himself and showed marked indications of returning muscular control. The drain was kept *in situ* for twenty-eight days and then removed; the removal was followed by an attack of sickness and general irritability, but these symptoms disappeared at the end of another week. On May 22nd the patient could stand against a wall without any assistance, and could raise himself into a sitting posture. On July 3rd he was reported by the mother to be able to stand without any support, to be able to say a great many words, and to show altogether many more signs of intelligence than he had previously displayed. On Jan. 8th, 1895, he was seen by Mr. Parkin among the out-patients; he could talk fairly well, recognise different objects and persons, and could walk if assisted with the hand. Since the operation he has grown two inches and a half, and the bodily increase in size, along with an absence of cranial increase, has almost removed the disparity which previously existed. When last seen by Mr. Parkin, in June, the improvement was even more marked.

CASE 2.—The patient, a male child aged five months, was admitted for fits and enlargement of the head on Aug. 20th, 1895. The circumference of the head was eighteen inches; the fontanelles and sutures were widely opened. The history pointed to congenital syphilis. There was double otorrhœa. The body was emaciated; the child was anæmic and took food badly. Basal drainage was set up on Sept. 3rd, and kept up by the insertion of a horsehair drain. For the next three days the child seemed very much better; a considerable quantity of fluid drained away, and everything seemed satisfactory. Four days after the operation vomiting set in, followed by a rise in temperature to 103° F., and death occurred from hyperpyrexia, due to the withdrawal of too much fluid, six days after the operation. Post mortem there was a general distension of all the ventricles, which still contained a considerable quantity of fluid. There were no septic changes about the wound, which was quite healed.

Remarks by Mr. PARKIN.—The very interesting and successful case of hydrocephalus treated by basal drainage—recorded in THE LANCET of Nov. 2nd, 1895—by Dr. Glynn and Mr. Thelwall Thomas has suggested to me the advisability of putting on record the above cases. The first case is instructive from the gradual improvement, dating from the operation, and perhaps more from the mental than from the bodily changes which have resulted. In the second case there appeared from the outset to be little chance of doing the child much permanent good, but it did not seem right to deprive him of the possible advantages from relief of the intra-cranial pressure which such an operation readily gives. The operation itself in children is extremely easy and can be readily done in ten minutes; in such cases there is generally instantaneous relief, as evidenced by alteration in the pulse and respiratory rates. The drainage is direct, and there is no necessary bruising of, or damage to, brain substance. I have operated so far in only four cases of tuberculous meningitis, and have not yet been able to come across a case where coma had not developed. It is obvious that in order to do good it is advisable, if not absolutely necessary, that operative measures should be undertaken in the early or irritative stage in order to ensure more successful results. In all the cases noted below the patients undoubtedly lost their distension pain, and life was prolonged from one to two weeks. The first case was that of a male child aged six months, with abdominal symptoms followed by convulsions rapidly passing into coma, the head symptoms having lasted for ten days before his admission. He was operated on six hours after he had become comatose and lived for twelve days after the operation. Post mortem there was found to be general tuberculosis, with tuberculous meningitis, the disease originating in the mesenteric glands. The second case was that of a female child aged three years. All the symptoms of tuberculous meningitis from caseous mediastinal glands, following whooping-cough, were present. She was operated on in the third week of the disease and was in a comatose state. She died four days later. No post-mortem examination was allowed. The third case was also that of a female; she was aged ten and was admitted for phthisis of the left apex, and for head symptoms of fourteen days' duration. She became delirious and unconscious, with marked symptoms of meningitis. She was operated on twelve hours after unconsciousness had supervened, and died ten days later. No post-mortem examination was allowed. The fourth case I have already recorded in the columns of THE LANCET.[1] The patient was operated on in deep coma, with Cheyne-Stokes breathing. The breathing became quite natural after the operation, death ensuing sixteen hours later.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Non-existence of Round-celled Sarcoma as a Distinct Class of New Growth.—Hæmatoporphyrin in the Urine after Administration of Sulphonal.—Relation of Biliary Calculi to Malignant Disease of the Liver.—Dermoid Tumour of the Testis.—Exhibition of Specimens.

AN ordinary meeting of this society was held on Nov. 5th, Mr. BUTLIN, President, in the chair.

Dr. SNOW read a paper on the Non-existence of Round-celled Sarcoma as a Distinct Class of New Growth. He said that a generation since the term "soft cancer" was loosely applied to any malignant tumour of soft consistence, no matter from what tissue it had sprung. At the present day the word "sarcoma" was frequently used in a similarly vague sense, and, in particular, "round-celled sarcoma" denoted almost any rapidly growing mass of round or oval cells whose origin was often doubtful. The lesions commonly so designated fell into three groups, and were either (*a*) carcinomata, (*b*) lympho-carcinomata, or (*c*) blastomata. Of the first, the huge encephaloid cancers of the female breast were the type. There was only slight concurrent enlargement of the axillary glands; examined at the core they consisted of a loose mass of cells and cell débris, with little acinar structure; a thin section, however, from the growing margin would display the familiar acini of mammary carcinoma. True sarcoma was rather rare in the breast, except in association with cysts. The second group, lympho-carcinoma, sprang from adenoid tissue in some form or other, to which appertained the bone marrow. As well as in the more external glands, the growth might be developed in those of the abdominal cavity and mediastina, in the tonsils, spleen, omentum, &c. The variety also comprised the central tumours of bone. The third, blastoma, sprang from uneffaced embryonic vestiges; it might very largely consist of round-celled parenchyma, but this was most commonly largely mingled with other structures, tubules, cysts, acini, &c.; its favourite sites were the kidney, ovary, and other derivatives of the Wolffian body. After careful study for many years past of all the specimens which presented themselves, Dr. Snow had been forced to the conclusion that no malignant tumour composed of round cells alone originated in the connective tissues; that every sarcoma, properly so called, contained much spindle-celled tissue, or spindle-cells ranged in bands and that none could be held genuine without this pathognomonic badge.—Mr. BOWLBY thought that the question at issue was really what names should be given to certain microscopic specimens; the specimens labeled lympho-carcinoma he should call sarcoma. The demonstration of the existence of melanotic carcinoma of the skin did not disprove the existence of primary melanotic sarcoma of that structure.—Mr. W. G. SPENCER said that melanotic papilloma was a common growth in pug dogs, and in old dogs it might develop into melanotic carcinoma. He deprecated the use of the term "blastoma," which was loosely applied to all kinds of new growth.—Mr. JACKSON CLARKE said that the

[1] THE LANCET, July 1st, 1893.

Digitized by Google

specimens labeled sarcomata he should put down as carcinomata.—The PRESIDENT remarked that there was no kind of disease about which there was so much difference of opinion as the round-celled sarcomata. Later we might have to make a division amongst these growths according to their origin, but we had at present no basis for forming such a classification.—Dr. SNOW, in reply, said that he was quite prepared to find that he had no supporters of his heresy. He had pointed out what he regarded as a straightforward definition of sarcoma, which was that this neoplasm, as the true offspring of connective tissue, was characterised by the occurrence of bands of spindle cells. He held that the very cells which secreted melanin in the skin were the cells of the Malpighian layer of the epidermis, and it was from these that the malignant pigmented growths of the skin sprang. In the eye melanotic sarcomata sprang from the pigmented connective tissue structures. The term "blastoma" was a convenient one to include a class of malignant growths derived from unobliterated fœtal rudiments which did not fall into the ordinary groups of sarcoma and carcinoma.

Dr. ARCHIBALD GARROD and Mr. HOPKINS contributed notes on the Occurrence of Large Quantities of Hæmatoporphyrin in the Urine of Patients taking Sulphonal. After pointing out that hæmatoporphyrin was present in traces in normal urine and in larger amounts in many morbid conditions, they proceeded to discuss its occurrence in much larger quantities still in the dark-red urine of some patients who had as a rule taken sulphonal for some time. The evidence connecting this with sulphonal was discussed, and an epitome was given of the associated clinical symptoms and post-mortem appearances in the published cases. The patients were nearly always women who had taken the drug without ill-effects for weeks, months, or even years previously. Abdominal pain and vomiting were prominent symptoms, and death in collapse frequently followed shortly upon the onset of the symptoms, which might only develop after the drug had been discontinued. Alkaline treatment appeared to have been useful in some cases. Clinical histories of three cases (of women taking sulphonal), supplied by Mr. J. Delpratt Harris, Dr. W. M. Abbot Anderson, and Mr. M. J. Nolan, were then given. All the cases ended fatally, but no post-mortem examinations were made. In one instance sulphonal had been taken for four years, and the symptoms only commenced ten days after the drug was stopped. A detailed account was then given of the general and spectroscopic characters of the dark-red urine of these patients. Tube casts were present in each instance. Even the trace of iron found in normal urine could not be detected. Various methods were employed for the extraction of the hæmatoporphyrin, and it was found that the soda and ammonium chloride methods, which worked so satisfactorily in ordinary cases, were quite unable to cope with the amount of the pigment present in these specimens. Repeated extraction with acetic ether was found very useful for the partial separation of the abnormal pigments present. In each instance the colour of the urine was only in part due to ordinary hæmatoporphyrin. In one case there was present much of a pigment derived from hæmatoporphyrin which yielded two absorption bands like those of oxyhæmoglobin. In a second case another derivative of hæmatoporphyrin was found, and in all the dark tint of the urine was largely derived from a reddish-brown pigment, such as was observed by Hammarsten, which yielded no spectroscopic absorption bands. The views of Stokvis as to the origin of urinary hæmatoporphyrin were referred to.

Mr. C. BEADLES read a paper on the Relation of Biliary Calculi to Malignant Disease of the Liver. He described the two chief theories which had been current to explain the coexistence of gall-stone with cancer of the liver. The first, which might be called the "irritation" theory, was that gall-stone was formed first and by acting as a foreign body set up irritation, which led to malignant growth. The second, or "concentration," theory stated that the gall-stone arose as a secondary result from stagnation of the bile in the ducts caused by their obstruction from malignant growth. The differences observed between primary and secondary carcinomatous growths of the liver as to situation and naked-eye characters were pointed out. Of 100 post-mortem examinations at the Cancer Hospital 4 were cases of primary carcinoma of the liver, and all had calculi in the gall-bladder; 36 had secondary carcinomatous growths in the liver, but there were no gall-stones present in any of them. Of 9 cases of primary carcinoma of the liver at Colney Hatch 5 were males and 4 females, and gall-stones were present in 7, being absent in 1 male and 1 female. These facts supported the theory of irritation, the carcinoma arising as a secondary result of the irritation produced by the presence of the calculi. A remarkably high percentage of insane people showed gall-stones post mortem, and in the majority there was no sign of co-existing inflammation of the gall-bladder or ducts.—Mr. SHATTOCK regretted that more histological detail was not given in the paper. If the carcinomata arose from irritation of the bile-ducts by calculus the columnar variety should be found.—Mr. W. G. SPENCER said that a clear distinction should be drawn between primary cancer of the liver and cancer of the gall-bladder.—Dr. VOELCKER said he had made 7 necropsies on cases of primary cancer of the liver and gall-bladder. In 2 cases the growth was primarily of the gall-bladder, a tubular carcinoma, and in both gall-stones were present. In 5 cases of primary cancer of the liver no gall-stones were present. In the post-mortem room of Middlesex Hospital last year 10 per cent. of the cases examined were found to possess gall-stones. In the cases in which evidence of irritation was present, such as adhesion and thickening, no cancer was found.—Mr. BEADLES, in reply, said that full details of the site of origin of the growths and of their histology were given in the paper.

Mr. JACKSON CLARKE showed a Dermoid Tumour of a Testis which had been presented to St. Mary's Museum by Surgeon-General Giles, who removed it from an infant aged one year. The following description of the growth was given. "A right testis containing a dermoid cyst as large as a hen's egg. The cyst is everywhere invested by the tunica albuginea; its cavity is almost entirely occupied by a large intra-cystic projection which springs from the region of the hilus and contains bone and cartilage. The remaining cleft-like space is filled with hairs and sebaceous matter. The microscope shows that the cyst is lined by skin containing pilo-sebaceous follicles and sweat glands. No trace of the tubules of the testis can be found in the loose areolar tissue which lies between the cyst wall and the albuginea, though the vas deferens and vessels are normal." The condition was a rare one, only one other case being recorded in the Transactions of the society—namely, by Mr. D'Arcy Power. The opinions of Lannelongue, Jacobson, Bland Sutton, and others were briefly discussed. As to diagnosis, cystic sarcomata occurring in infancy were alone likely to give even a superficial resemblance to the condition in question. When the cyst formed in the interior of the testis the treatment was that practised by Surgeon-General Giles in this case—namely, castration.

The following card specimens were shown:—
Mr. BEADLES: Ureter obstructed by Calculus.
Dr. WILLCOCKS: Perihepatitis and Thrombosis.
Dr. WALSHAM: Pulmonary Stenosis.
Mr. EDMUNDS: Myxoma of Breast.

ÆSCULAPIAN SOCIETY OF LONDON.

Urethral Stricture with complications.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 1st, Dr. R. F. WILLOUGHBY, President, being in the chair.

Dr. C. G. MACK read notes of a case of Urethral Stricture with complications in a man aged seventy-two years. The stricture was of twenty-three years' duration, and led to the formation of a peri-urethral abscess with consequent perineal fistula. A period of catheterisation followed. A year and a half ago rapid dilatation by means of graduated bougies was carried out until a No. 12 passed the stricture. The urine contained pus and also casts of renal epithelium. Four months later a large perineal abscess formed and was opened, urine passing through the fistula, and this was followed by the formation of others of small size. For a time the patient improved, but retention followed and was accompanied by persistent hæmorrhage from the urethra and fistulæ. While in this condition a soft rubber catheter was passed, tied in, and removed daily, the bladder being washed out with weak Condy solution followed by a copious douche of boric acid. Under this treatment all troublesome symptoms disappeared and the patient was able to micturate freely and to follow his occupation. The syphon douche was used.

Dr. J. T. CONNER showed two cases of Pigmentation of the Lips and Mouth in twins, both girls, aged twelve years, of dark complexion and anæmic. The pigment spots, which were only noticed two years ago, were of ink-black colour, mostly of very small size, and scattered over the lips (especially the lower), gums, and hard palate, but not on the tongue.

Dr. CONNER also showed a case of Chronic Ptyalism (hygrostomia) in a woman aged sixty-eight. It had lasted for ten years without intermission. The flow occurred at night as well as in the day. In fact it was greater when the patient was in bed, and considerably interfered with sleep. The secretion of one night was shown. It was an opalescent fluid with a cloudy viscid deposit and amounted to 3 oz. The reaction was acid, the specific gravity 1006, and it readily converted starch into sugar. The patient had lost all her teeth and did not use artificial ones. The mouth was unduly moist; otherwise there was nothing abnormal and her general health was good. Dr. Conner believed that this form of salivation had not been previously recognised; but he had found a case anonymously recorded[1] which curiously corresponded to his in almost every particular—age, sex, absence of teeth, and preservation of the general health. He also compared these cases with the opposite condition (xerostomia), which in all other respects they resembled.

Dr. A. K. CHRISTIE showed a specimen of Fatal Endocarditis in a female child aged nine years. She belonged to a generally healthy family, only one member of which suffered from rheumatism. The patient's personal history was absolutely free from any rheumatic taint. She appeared to be well on Oct. 2nd, became suddenly drowsy towards evening, and died the next morning. A post-mortem examination showed the viscera to be generally healthy but for the evidences of old and recent endocarditis, especially on the mitral valve. There was also a softened patch on the anterior wall of the left auricle studded with small soft vegetations. Embolism from the detachment of one such vegetation was suggested as the cause of death.

Dr. B. G. MORISON showed specimens of Branching Casts of Plastic Bronchitis expectorated with some hæmorrhage by an elderly man of rheumatoid type.

ISLINGTON MEDICAL SOCIETY.

Acute Inflammation of Bone.—The Islington Workhouse Infirmary.

A MEETING of this society was held on Oct. 22nd, Dr. WHITE being in the chair.

Mr. BATTLE read a paper on Acute Inflammation of Bone as it is met with in children over five years of age. He divided the cases met with into three classes according to their severity, and gave the principal points which assist in diagnosing the condition from other diseases. He then discussed the treatment, advocating very strongly an early incision through the periosteum without waiting for fluctuation, in order that the fever might be cut short, necrosis prevented or much limited in extent, suppuration in joints prevented, and the risk of pyæmia minimised. He gave examples from his practice to illustrate this part of the subject, and showed a patient. The treatment of these cases when a joint was invaded was now considered and conservative measures advocated. The endurance of these patients was commented on, and examples given to show the good result which may follow patient treatment in some instances. Two cases were shown, both of which had been under care some years ago. One had ankylosis of the knee in consequence of extension of the inflammation through the epiphysis to the joint. The other had perfect use of the knee-joint, which had suppurated and been drained four years ago. Each had had extensive necrosis of the tibia. In the one there had been no growth at the upper end of the tibia since the sequestrotomy. In the other, where suppuration in the joint had resulted, growth of the tibia had continued unimpaired. In one case mentioned the patient recovered after suppuration in the knee, ankle, and big-toe joints.

On Oct. 30th a special meeting of the society was called to consider the duty of the society in respect of the present crowded condition of the infirmary and its insufficient medical staff. The following resolution was passed: "That the members of the Islington Medical Society desire to express their deep concern at hearing of the overcrowding of the Islington Workhouse Infirmary and the admitted insufficiency of the medical staff in attendance on the sick. Having in the course of their professional duties to advise poor patients to go into the infirmary, they cannot but feel much hesitation in doing so if such a state of things continues. The Islington Medical Society would respectfully urge upon the board of guardians to take immediate steps to remedy the overcrowding in the wards, and to provide such additional medical, dispensing, and nursing assistance as the great number of patients in the infirmary really needs."

[1] THE LANCET, April 9th, 1892, p. 845.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Ætiology and Treatment of Gastric Ulcer.

A MEETING of this society was held on Nov. 1st, Dr. A. SYMONS ECCLES, President, being in the chair.

Dr. DONALD HOOD, in opening the discussion from the medical standpoint, said his remarks would be confined especially to considerations on diagnosis in those cases where symptoms are indefinite, ambiguous, and often misleading. He would refer to the importance of weighing well the value of the symptom hæmatemesis, and he would draw special attention to the careful differentiation between various forms of acute abdominal pain with a view to diagnosis at the earliest possible moment of the existence of perforative ulcer. He proceeded to give a brief clinical picture of the most important subdivisions of groups under which gastric ulceration practically came before practitioners for treatment. He cited a case which had been judged to be one of merely prolonged dyspepsia, but which an examination after death proved to have been one of extensive recurrent ulceration, producing much contraction of the stomach and leading to perforation of the diaphragm. He referred, also, to a case of acute perforation and severe hæmatemesis in a young anæmic girl, and in connexion with this he adduced certain criteria which would help to differentiate cases of hæmorrhage caused by organic breach of the stomach walls from those which frequently occurred in early adult female life without any such breach—a condition for which he proposed the name "hæmatemesis puellaris."

Mr. BRUCE CLARKE, introducing the surgical side of the discussion, began by referring to the rarity of perforations of gastric and duodenal ulcer. He described two principal varieties, those in which collapse was the prominent symptom, and a second variety in which the extravasation of intestinal or gastric contents was more gradual. These cases were often indistinguishable from intestinal obstruction, and, indeed, gave rise to it by the peritonitis which they set up. There was only one keynote to success in ruptured ulcer and that was early diagnosis and early treatment.

Dr. F. H. ALDERSON thought that gastric ulceration when unaccompanied by hæmorrhage and vomiting was frequently overlooked. He commented on the rarity with which gastric ulcer was assigned as a cause of death, and quoted the Hammersmith statistics for five years, where out of 8305 deaths only 11 were assigned to this cause. He narrated a fatal case from his own practice in which at an early stage, owing to the absence of definite symptoms, diagnosis was impossible. In this case the patient was an adult male.

Dr. SEYMOUR TAYLOR spoke only of that form of ulcer which is found almost exclusively in young women and is clean and punched out in appearance. He argued that this was an almost constant incident in the clinical history of prolonged cases of chlorosis, and cited authorities who had noticed this connexion. He pointed to the common factors of age, sex, and neurosis, and held that neuropathy was the starting point in chlorosis. Further, the ulcer in its appearance and character approaches those ulcerations which are distinctly neuropathic, tabetic ulcers, herpes, &c. He held that the connexion was further established by treatment. He maintained that the embolic theory was untenable in view of the splendid collateral circulation of the stomach.

Dr. CAMPBELL POPE called attention to the remarkable rarity of gastric ulcer among certain vegetarian populations. For treatment he preferred belladonna to opium in the earlier stage, and later he used arsenic and iron.

Mr. KEETLEY contrasted the signs of perforation in various situations, and advocated early operation, even at times without waiting for recovery from shock and without an anæsthetic.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Chronic Nasal Obstruction.

A MEETING of this society was held on Tuesday last, Dr. ERNEST CLARKE, President, being in the chair.

MR. MAYO COLLIER read a paper on the above subject, in which he reminded his audience of the extraordinary frequency of the condition. He next showed that this state of things was seldom or never congenital, but was progressive, commencing at or about the time of puberty to increase with the development of the parts. Having enumerated a long list of affections the direct outcome of obstruction to the nasal passages, he pointed out the serious and irreparable damage often done to the young growing skull by leaving things to themselves. Moreover, the symmetry of the face and beauty of the countenance were in many cases lost or impaired. The commonest effects on the growing skulls of young persons were a pinched and flattened or hatchet-shaped appearance of the face, comparative smallness of the upper jaw, high, arched palate, with crowded and irregular teeth. Associated with this were often general anæmia and stunted growth.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Oct. 24th, the President, Dr. PORTER, being in the chair.

Mr. SNELL introduced: 1. A woman with Embolism of the Central Artery of the Retina; she had mitral and aortic disease. 2. A man aged forty-eight with Extreme Myosis, Argyll-Robertson Pupils, and loss of Knee-jerks. He had been under observation for years in practically the same condition. 3. A man with Traumatic Palsy of both Sixth Nerves. Mr. Snell drew attention to the cases of traumatic palsy on record, specially mentioning the valuable papers of Purtscher and Friendwald. It appeared that the other cranial nerves were more liable to suffer from trauma than the sixth pair, and when the latter did suffer other nerves were implicated. Altogether fifty-seven cases were on record, and seventeen were bilateral. 4. A girl with Bilateral Palsy of External Recti and Double Papillitis. Headache and sickness were the other symptoms suggesting some intra-cranial growth.

Dr. SINCLAIR WHITE exhibited and related particulars of: 1. A case of Trephining for Temporo-sphenoidal Abscess due to Suppurative Middle-ear Disease. An abscess containing two ounces of offensive pus was cleared out and disinfected, but in spite of this the patient got worse. Four days later the wound was reopened, more bone removed, and a second independent abscess discovered and treated. Although the lad appeared to be *in extremis* he rapidly recovered after the second operation, and is now quite well except for his deafness. 2. A large number of Gall-stones removed from a Suppurating Gall-bladder. Owing to the distended gall-bladder being bound down by omental adhesions it was not in contact with the anterior abdominal wall. This fact, conjoined with absence of history of hepatic colic, rendered a diagnosis difficult prior to exploration. The patient, a woman aged fifty-three, made a good recovery. 3. A girl aged seventeen years, from whom the Right Astragalus had been removed eighteen months previously for a myeloid sarcoma. Excision was done through a single external wound. The resulting foot was both shapely and useful, the girl being able to walk several miles without fatigue. The arch of the foot was preserved, and, contrary to what is generally taught, there was considerable movement at the new ankle-joint. Dr. White had not been able to find a case of excision of the astragalus for tumour on record.

Mr. DALE JAMES introduced a case of Paraffin Acne. The patient was a boy who worked in a wire mill, where, the wire having been hardened in a tank of crude paraffin, he had to make it up into rolls. Hence his clothes became saturated, and the eruption appeared about a month after he began this work. Three other boys working in the same mill are similarly affected. The eruption is chiefly on the legs, on the anterior and lateral aspects, and on the forearms. It is confined to the follicles and presents various appearances—i.e., a black plug filling the follicular opening; a second stage in which the plug is raised at the summit of a papule; further in which the papule is inflamed, and again when this is surrounded by a flush; and, finally, there are several places in which a very small fleshy tumour is substituted for the papules. Innumerable minute scars mark the seats of past lesions.

Dr. ARTHUR HALL showed two cases of Syphiloderma and one of Circumscribed Scleroderma.

Dr. BURGESS showed a case of Xanthoma Multiplex. The patient had been jaundiced for over a year from hypertrophic cirrhosis of the liver.

LIVERPOOL MEDICAL INSTITUTION.

Large Vesical Calculus.—A Method of producing Rapid Delivery in Puerperal Eclampsia.—Villous Tumour of the Bladder.—Professor Fraser's Snake-bite Antidote.—The Subsequent History of twenty-three cases of Typhlitis.

AN ordinary meeting of this society was held on Oct. 31st, Mr. CHAUNCY PUZEY, President, being in the chair.

MR. GEORGE HAMILTON showed, as a card specimen, a Vesical Calculus which he had removed and which weighed over half a pound.

Dr. T. B. GRIMSDALE related a case in which he had induced Rapid Delivery by deeply Incising the Cervix Uteri. The patient was suffering from Puerperal Eclampsia. Before the operation the os would just admit the finger; after the incisions were made the forceps could be easily applied, and a living child was extracted in three or four minutes. The incisions were four in number, radiating from the os and extending through the cervix to the vaginal reflection. After delivery the fits diminished, and in twenty-four hours the patient had regained consciousness, but four days later she became maniacal and did not recover from this for five weeks. The albumin disappeared from the urine on the third day.—Dr. BRIGGS considered that where rapid delivery was easy and the cervix thinned and moderately dilated there could be no objection to speedily emptying the uterus, but thought that in many cases rapid withdrawal of the uterine contents would not be desirable.—Dr. IMLACH and Dr. DAVIES also made remarks on this case.

Mr. NEWBOLT showed a young man aged twenty-one years who had been under his care since June, 1894. For three years he had complained of great pain during micturition, with sudden stoppage of the flow and the frequent passing of blood. A sound detected a soft substance in the bladder, which bled readily. The bladder was opened above the pubes on several occasions, and a quantity of villous growth could be seen surrounding the orifice of the urethra and covering the whole surface of the mucous membrane except at the summit of the bladder. Removal of considerable portions of the tumour was made from time to time by a Volkmann's flushing spoon, the severe hæmorrhage being controlled by very hot water. The last operation was performed in April of this year, and the patient was now much improved in every respect, but still suffered from frequent sharp pain in the left loin. This pain, Mr. Newbolt thought, was probably due to contraction of the orifice of the ureter or blocking of it by growth. There was now no pain during micturition or bleeding, but there was a small deposit of pus.—Mr. PAUL, Dr. BRIGGS, and Dr. ROSS made remarks on this case.

Dr. LOGAN showed Professor Fraser's Anti-venine both as a liquid serum and in the crystalline form.—Mr. NICHOLSON said there was no doubt as to the scientific value of Professor Fraser's work, but he questioned whether the antidote would have any practical value in India. Considering the enormous population of India, death from snake-bite was very infrequent. Every case of snake-bite was not necessarily fatal; on the contrary, numbers of persons recovered, and various antidotes gained great credit in consequence.

Mr. R. W. MURRAY divided his twenty-two cases of Typhlitis into three groups. They were all collected from the records of the Children's Infirmary, Liverpool, since 1886. The numbers by no means represented all the cases treated during that period, but those of which he had notes and whose subsequent history he had been able to trace. With one exception no case was more recent than two years ago. He then gave the groups as follows: 1. Nine patients in whom there was inflammation of the vermiform appendix, with, most probably, a slight and strictly localised peritonitis; these all recovered under medical treatment and remained well, though three of them were relapsing cases; the

Digitized by Google

period that has elapsed since their admission varied from three to seven years. 2. Ten cases, where there was a localised peritoneal abscess due to inflammation of the appendix in which the abscess was simply opened and drained; nine of the children remained well, the time which has elapsed since operation varying from three to six years; one died from suppurative peritonitis owing to an accident during the syringing of the wound. 3. Three cases where the appendix rapidly became gangrenous and perforated; they all died.—Dr. GLYNN referred to the difficulty sometimes experienced in distinguishing between chronic inflammatory induration in the region of the cæcum and malignant disease of that part. He believed that the inflammatory cases commenced with acute symptoms, pain, and constipation, whereas in malignant disease there was often diarrhœa with discharges of blood and mucus.—Mr. RUSHTON PARKER said that, where perforation of the appendix occurred, general septic peritonitis and death speedily resulted. He had seen several cases of typhlitis in adults where the question of abdominal section was raised, but recovery took place under rest and opium. He was convinced that promiscuous operation was not indicated in typhlitis, whether attended by intestinal obstruction or not.—Mr. PAUL thought that in adults there was undoubtedly a class of cases which could not be freed from a recurring danger without operation, whilst the operation, if undertaken at the right time, was almost always successful and devoid of risk.—Mr. RAWDON said that during the time he was surgeon to the Children's Infirmary all cases which suppurated did well, and he could not remember a single instance of recurrence.—Mr. LARKIN remarked that in his opinion the recurrent cases of appendicitis were a distinct clinical group, and only to be cured by removal of that structure.—Mr. A. DAVIS referred to the injurious effects of purgatives and the marked beneficial effects of opium in these cases.—The PRESIDENT, Dr. BANKS, Dr. P. DAVIDSON, Dr. BOYCE, and Dr. ABRAM also took part in the very interesting discussion on Mr. Murray's paper.

PLYMOUTH MEDICAL SOCIETY.

Otorrhœa and some of its Complications.

AT the meeting held on Oct. 26th the Hon. Secretary read (in the absence of the author) Mr. CHAS. E. BEAN'S paper on the above subject. The writer confined his remarks to the salient features of chronic purulent otitis media and its more usual complications. The records of the Devon and Cornwall Throat and Ear Hospital showed that out of 2160 aural cases 660, or 30·5 per cent., were classed as "otorrhœa." The gravity of its effects were shown by the figures of the Registrar-General, wherein from 300 to 400 deaths are annually returned as due to "otitis." Mr. Bean then proceeded to the symptoms, course, and treatment of cases of chronic purulent otitis media, emphasising the need for drying the middle ear thoroughly after antiseptic irrigation; the careful use of the curette when removing granulations, carious bone, and fragments of membrana tympani; and the use of cocaine as a hæmostatic. The complications described were perforation of membrana; polypi; caries and necrosis of temporal bone, with abscess of parotid gland, especially in children; implication of the mastoid antrum and cells, and the indications for operation; and intra-cranial diseases, including (*a*) extradural abscess, (*b*) meningitis, (*c*) cerebral and cerebellar abscess, and (*d*) sinus phlebitis, associated with which may be thrombosis of the internal jugular vein and ulceration of the internal carotid artery.

In discussing the paper, Mr. ELLIOT SQUARE pointed out the value of instilling cocaine previously to operating under a general anæsthetic, both to check hæmorrhage and to prevent movements during imperfect anæsthesia.

Mr. LUCY exhibited a specimen of the Left Temporal Bone removed from a boy aged five years, which showed the large size of the mastoid antrum, its porous roof, and the small size of the mastoid process and the absence of cells.

Mr. WEBBER urged the part played by post-nasal adenoids in causing otorrhœa, and cited an interesting case of hæmorrhage from both ears (recorded in THE LANCET of March, 1894).

Dr. RIDER concurred as to the frequent association of adenoids and otorrhœa, urged the cautious use of chromic acid, and pointed out the dangers of plugging the meatus with powders or wool.

Mr. WOOLLCOMBE recommended the more frequent clearing out of the mastoid antrum and cells previously to other operative measures.

Mr. WHITEFORD cited septic affections of the pharynx as causes of otorrhœa, and urged the advisability of clearing out thrombus from the lateral sinus and internal jugular vein.

Reviews and Notices of Books.

The Growth of the Brain: a Study of the Nervous System in relation to Education. By HENRY HERBERT DONALDSON, Professor of Neurology in the University of Chicago. London: Walter Scott and Co. 1895. Price 5*s*.

THIS volume is one of the excellent Contemporary Science Series, edited by Mr. Havelock Ellis, and contains a very large number of facts of great interest, which are, no doubt, for the most part gathered from well-accredited sources, but which it is extremely convenient to have at hand in a collected series and in a well-arranged form. It is indeed in the arrangement of large masses of facts and statistics and in the demonstration of their connexion with each other that the chief value of a work like this consists, and we can say with confidence that Professor Donaldson has executed his work with much care, judgment, and discrimination. The introductory chapter describes the nature of a cell and the process of fertilisation. He refers to the recent calculations of Francke that the human body contains, including the blood corpuscles, rather more than twenty-six billion—or million million—cells, an amount which, although inconceivably great, yet, supposing each cell to be 1000th of a cubic millimetre, might be contained in a cube having a side of 2·8 centimetres (about $1\frac{1}{10}$ in.), or in a space of 22·5 cubic centimetres. The power of growing seems to be closely connected with length of life, but as yet there is no adequate explanation of the fact that some animals live longer than others; and, as the larger animals have longer lives, long life is associated with size, and the author points out that size depends upon two factors: the rate of growth and the length of time that growth continues—so that animals that attain a large size grow both rapidly and for a long time. A table that is given shows that the rate of increase in the rabbit and in man is about the same, but, owing to the fact that in man growth continues for about twenty-five years, whereas in the rabbit it stops at the end of one year, the difference in the final size of each is very great. Since, then, natural death is the result of old age; since, further, old age is not attained until growth has been completed, and large size depends on long-continued growth: therefore long life and large size are found associated. From the moment of birth there is a rapid falling off in the proportional daily increase in the body-weight in all the higher animals—a time soon comes when increase ceases, and the body then becomes more susceptible of destructive influences. With the decay of any part of the organism comes a disturbance of the balance in the work allotted to other portions. Tissues not specialised for the purpose are compelled to discharge the functions of those already damaged and perform them but imperfectly. The result is progressive enfeeblement of these overtaxed cells, until finally some function is so imperfectly performed that the life processes are blocked and the organism as a whole dies. Minot pointed out that in the mature cell the proportion of cytoplasm to nucleus is greater than in the growing animal, and on this ground he propounds, half humorously, the aphorism that "protoplasm is the physical basis of advancing decrepitude." We have reproduced the above sentences in a somewhat abbreviated form from Professor Donaldson's work, but they suffice to show that he writes well and clearly. Succeeding chapters deal with the increase in weight

Digitized by Google

of the entire body (in which the tables of Dr. Charles Roberts are taken as a guide, because, unlike those published in Denmark, Germany, Sweden, Russia, and the United States, they include the ages before four and after twenty, which are not given in foreign statistics since the latter deal only, or chiefly, with school children); with the weight, increase of different parts of the body, and increase in stature; with the weight of the brain and spinal cord, and the capacity of the cranium; with the histology of the nervous system; with the localisation of function in the brain; with physiological rhythms; with fatigue and old age; and with the education of the nervous system. This last chapter is a very thoughtful and suggestive one, and we are tempted to make a short extract from it. "It is extremely interesting," the author says, "to see how in a series of eminent men, excluding men of action, the determination of distinction follows the order in which the brain normally attains the high development necessary to command recognition in a particular profession. The manner in which the encephalon becomes organised shows that some combinations among the central elements are normally completed earlier than others. When, however, such sensori-motor connexions are once established the time required for their perfection is comparatively short. Further, it appears that high excellence, especially in the acts requiring simple sensori-motor combinations, is acquired speedily or not at all; and thus prolonged exercise, though it may have value as a moral training, is insignificant for technical improvement." Professor Donaldson gives a table from Sully which shows that amongst 287 men of eminence those who gave promise earliest, produced in their own art earliest, and distinguished themselves earliest might be ranked in the following order: musicians, artists, scholars, poets, men of science, novelists, and philosophers. The work throughout is very readable and constitutes a valuable addition to the series of which it forms a volume. It may be read with advantage by all engaged in the tuition of the young.

A Manual of the Practice of Medicine. By FREDERICK TAYLOR, M.D., F.R.C.P. Lond., Physician to, and Lecturer on Medicine at, Guy's Hospital. Fourth Edition. London: J. & A. Churchill. 1895.

THE rapidity with which new editions of a text-book are called for is unfailing evidence of its merits and its suitability to the student's needs. Of text-books in medicine there is indeed no lack, and therefore it is all the more gratifying to find that so comparatively a new-comer as "Taylor's Medicine" should have obtained within five years the distinction of a fourth edition. The author is to be congratulated on this practical proof of the popularity of his work—a popularity which is thoroughly well deserved. Nor has he been unmindful of the duty, incumbent on every teacher in these days of rapid additions to knowledge and changes in thought, to carefully revise his work, so that it may keep abreast of the times. He says in his preface that in the section on specific infectious diseases "I have endeavoured to represent the latest views and discoveries; and the questions of immunity, protective inoculation, and antitoxins have received attention." Space is also given to a fuller account of tropical diseases, whilst chapters have been introduced on Acromegaly and Mycosis Fungoides. And as another striking example of revision of medical opinion the "subject of appendicitis has been largely re-written." It would be a work of supererogation to submit this text-book to any detailed critical analysis. Its author is well known as an accomplished physician, and his teachings are evidently based upon wide clinical experience. The result of his labours is a work which can safely be recommended as a trustworthy and reliable guide to the principles and practice of medicine.

Surgery: its Theory and Practice. By WILLIAM JOHNSON WALSHAM, F.R.C.S. Eng., M.B., C.M. Aberd., Senior Assistant Surgeon, Lecturer in Anatomy, and Surgeon in charge of the Orthopædic Department, St. Bartholomew's Hospital, &c. Fifth Edition. With 380 Illustrations. London: J. & A. Churchill. 1895.

IN preparing the fifth edition of this work the author states that he has endeavoured to increase its usefulness by amplifying those subjects that seemed to require it and by describing many conditions and operations not mentioned in former editions. This, we learn, has been done without materially enlarging the book by leaving out such matter as, with the advance of surgical science and practice, has now ceased to be of value. The character of the type is improved and more illustrations are added; some of these are, however, superfluous, such as No. 269, the diagrams to show the lines of incision for the arteries of the extremities are useless, and No. 289 is a reproduction of No. 146. Altogether this edition is, however, considerably improved. We still hold that the true use of a book such as this is for men at the close of their student career, when, having firmly grasped surgical principles, they want to freshen their memories on the details of surgical injuries and diseases. It is not, in our opinion, well adapted for the student, in whose hands it is probably used as a "cram." We know that it is liked by the student from the frequency with which we see it carried about, but we regard it as inadequate to supply the knowledge required by one who is studying surgery as an important part of professional education. Our experience is that few students buy more than one book on surgery, and we contend that such a subject should be more fully treated than it can be in a volume of the size of this one.

Verhandlungen des Congresses für Innere Medicin. Herausgegeben von Dr. E. LEYDEN und Dr. EMIL PFEIFFER. Dreizehnter Congress. Wiesbaden: Verlag von J. F. Bergmann. 1895. (*Transactions of the Congress of Internal Medicine.* Edited by Dr. E. LEYDEN and Dr. EMIL PFEIFFER. Thirteenth Congress. Wiesbaden: J. F. Bergmann. 1895.)

ONE of the most interesting and most fruitful of the annual medical congresses that now so plentifully abound is that of "Innere Medicin," which for many years used to meet regularly at Wiesbaden. It always assembles in the spring of the year, and one of its chief features is the selection beforehand of two or three topics of current interest for general debate. The meeting last spring was at Munich under the presidency of Professor von Ziemssen, and the published volume of its Transactions contains much that is noteworthy and valuable. Thus the first day's subject was the Serum Treatment of Diphtheria, which was introduced by Professor Heubner of Berlin, and discussed by a large number of physicians from all parts of Germany. The next debate was on Iron in Therapeutics, opened by Professor Bunge of Basle and Professor Quincke of Kiel; whilst the third was upon the Pathology and Treatment of Typhlitis (*lit.*, the "typhlitides"), opened by Professor Sahli of Berne and Professor Helferich of Greifswald, who were followed by Dr. Sonnenburg, who gave a very instructive account of his experience of "Appendicitis Simplex." Many memoirs on subjects of more or less clinical importance make up the volume, which strikes us as being one of the most valuable and interesting that has appeared amongst the thirteen that have been published since the Congress was instituted. We may have occasion to refer again to some of these articles.

LIBRARY TABLE.

Circular Sewer Discharges. By a MUNICIPAL ENGINEER. London: The St. Bride's Press, Limited. 1895. Price 1*s.*—For the municipal and prospecting engineer this is an

Digitized by Google

indispensable table, in the form of a handy pocket-book, giving the discharge from circular sewers at different gradients, when running full, in cubic feet per minute. The figures are based on a calculation of the formula of Weisbach, in which the chief factors are head of water in feet, length of pipe in feet, diameter of pipe in feet, velocity in feet per second, coefficient for friction, and coefficient of resistance for entrance of water into pipe. Thus at a glance the engineer can get just the information he wants in regard to the capacity and flow of sewers when preparing new schemes of drainage.

Examination of Water for Sanitary and Technical Purposes. By HENRY LEFFMANN, A.M., M.D., Ph.D. Third edition, revised and enlarged, with illustrations. Philadelphia: P. Blakiston and Co. 1895. Price $1.25.—Since the issue of the first edition of this useful little work we have employed several of the processes described therein for the analysis of water in our own laboratory, with results which occasion us no surprise that in a very short space of time there has been a demand for three editions. The present edition has been revised entirely by Dr. Leffmann, his former colleague, Dr. William Beam, having left to reside in a distant part of the world. The book is quite in touch with recent progress, as is instanced in the observations on useful and worthless filters, while much of the text in the section on Biological Examination has been rewritten in harmony with modern notions. To the English reader its only blemish is its American orthography. The plural of sulphide is written "sulfids," and so on. That this system is not consistent, moreover, is evident from "chlorin" and "urine."

Elements of Modern Chemistry. By the late CHARLES ADOLPHE WÜRTZ. Fifth American edition. Revised and enlarged by WM. H. GREENE, M.D., and HARRY F. KELLER, Ph.D. Philadelphia: J. B. Lippincott Company. London: 10, Henrietta-street, Covent-garden. 1895.—The author of this volume was the editor of the well-known "Dictionnaire de Chimie," supplements to which, we believe, continue to be published. His knowledge had extended far into every branch of chemical science, and fresh facts, as they were brought to light from time to time, could hardly have escaped his notice. Had it been otherwise we should have been surprised to find that what is nowadays a really difficult task—namely, to include the whole of the leading and most important facts of both organic and inorganic chemistry, to say nothing of the treatment of the theoretical portion, within the convenient dimensions of such a volume—had been so successfully accomplished. But Würtz was not only a master of chemical science but a teacher and a writer, and we are glad that the simplicity of his own language has been preserved so far as the exigencies of translation would permit. The plan of treatment of the subject is old, but nevertheless good. The student must grasp the mathematics of chemistry and pass over the *pons asinorum* before he so much as handles a test-tube. Thus the laws of chemical combination and of definite proportions, the atomic theory, and the system of nomenclature are his first intellectual exercise. It is interesting to find a paragraph devoted to argon in the section on Air, giving a description of its preparation and properties. It is the first reference we have found in text-books to the newly discovered constituent of the air. While this affords evidence that care has been taken to include the latest advances in inorganic chemistry, we see the same fact brought out in the organic section, where space has been found for a description of the new antipyretics which organic chemistry has placed at the service of the physician, as exemplified in antipyrin, phenacetin, and thalline. Indeed, the section on Organic Chemistry is, consistently with the size of the volume, very fairly complete, and concludes with some excellent paragraphs on the alkaloids, albuminoids, albumins, biliary principles, and other bodies of physiological importance and of general medical interest. Würtz commenced as a student of medicine, and medico-chemistry was a subject of special interest to him. The book may be recommended as an excellent manual on chemistry for students of medicine to read in the earlier part of their curriculum.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE ordinary quarterly Comitia of the College took place on Oct. 31st, the President, Sir J. Russell Reynolds, Bart., being in the chair.

J. H. Dauber, M.B. Oxon., M. S. Löwenthal, M.D. Würzburg, E. S. Smith, M.D. Durh., and H. C. Thomson, M.D. Lond., were admitted to the Membership of the College.

Licences were granted to the successful candidates at the recent examinations of the Examining Board.

On the motion of Sir R. Quain the use of the library was granted to the General Medical Council for the purpose of its next meeting.

Two communications were received from the Colonial Office, one conveying a report on the sanitary condition of Hong-Kong, and the other enclosing a despatch from the Straits Settlements relative to the alleged discovery in Java of a supposed remedy for diphtheria.

A report was received from the University of Edinburgh awarding the Murchison scholarship to Mr. Neil Macvicar, M.B.

A communication was read from Mrs. Blenkins, widow of the late Deputy-Inspector-General Blenkins, offering for the acceptance of the College the collection of anatomical and pathological preparations which he had made, chiefly from specimens obtained in the Crimea. Mr. Blenkins in 1851 had received the thanks of the College for work done in its museum. The offer was referred to the museum committee for consideration and report.

Sir Dyce Duckworth briefly reported the circumstances of his representation of the College at Paris on the occasion of the State funeral of M. Pasteur.

The audited accounts for the year ending Sept. 29th were laid on the table, and reports from the finance committee, the committee of management, and the laboratories committee were received and adopted.

Dr. Ord was re-elected a member of the committee of management, and Dr. Pye Smith of the laboratories committee.

SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.—In the recently issued statement of the Bristol branch of this society it is stated that since 1889 it has investigated 2200 complaints of cruelty in Bristol and the neighbourhood, affecting 42,000 children. In cases where the complaints were well founded, and this was generally the case, the offenders were warned, and then, if necessary, prosecuted. The actual number of prosecutions had been 300, and only 12 had been acquitted, this being below the average of acquittals of the society throughout the country. Up to the end of 1894 the number of cases investigated in this district exceeded that in any other district of England except London.

THE MEDICAL GUILD, MANCHESTER. — The quarterly meeting of the Medical Guild was held in the Victoria Hotel on Oct. 31st, Mr. Alderman Walmsley, J.P., being in the chair. At the previous meeting the Council of the Guild was asked to report generally on Provident Medical Aid. An interim report was now read, dealing with the Friendly Societies' Sick Clubs, Provident Dispensaries, and Medical Aid Associations. After discussion the report was referred back for completion, and ordered to be then printed, and a copy sent to each member of the Guild one month before the next quarterly meeting. On the motion of Dr. Brierley it was by a majority resolved that the council be instructed to draw up a scheme of provident medical aid on the basis of a wage and age limit, constructed on a sliding scale.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, NOVEMBER 9, 1895.

THERE is a general feeling throughout the profession in favour of a more strict enforcement of the principles and duties of medical ethics. The profession is crowded as it never has been before, and the temptation to resort to undignified and unprofessional methods is greater than it has ever been; but the general antipathy of medical men towards such methods continues, and is likely to continue. Our profession is not a well-organised one. Its great corporations are only beginning to realise their duties to their members. And the voluntary associations of medical men are still far from acting with that clearness and cohesion which are necessary to make an effective impression either on the profession or on the public outside. Progress, however, in every direction may be noted. At its last annual meeting the British Medical Association devoted quite an unusual amount of attention to such subjects. It imposed by resolution on its council the duty of approaching Government, the General Medical Council, Parliament, teachers of medicine, and others in support of measures for the better regulation of medical conduct. We do not pretend to know how far the council is giving effect to these resolutions; but it will be called to account if it does not soon give evidence that it is endeavouring to give effect to them. A still more satisfactory sign of the steady progress of the profession in regard to medical conduct and methods of practice is to be seen in the reports of our Special Commissioner from various important towns under the heading of "The Battle of the Clubs." The essence of all medical ethics is the recognition that the individual practitioner in the last resort is the custodian of the honour of the profession, and that he is bound to do nothing to tarnish it either personally or through the agency of bodies or societies. The unity and organisation of the profession in most of the towns our Commissioner has visited are altogether admirable. We can only desire to see this example followed in every town and in every country district. Neither the General Medical Council nor the medical corporations can help medical men who will not use their own local authority in an organised and dignified manner for the assertion of medical rights and in condemnation of those members of the profession who are willing to betray its general interests if they can gain a personal advantage.

If medical men will organise in their several localities they will be more respected by the public, and they will create an *esprit de corps* that will have the most beneficial effect on those who are tempted to forget that they are members of a liberal profession that deserves to be treated respectfully in a civilised and self-respecting community. They will, moreover, leave little to be done by the medical authorities in the way of vindicating medical ethics.

Still, it is of the first importance that these authorities should have full power of controlling their members whenever th ir conduct exceeds that which is incapable of correction by the expression of local medical opinion or of the larger voluntary associations of the profession. The Royal College of Surgeons of England has set an excellent example to the other corporations in obtaining the sanction of the Home Secretary to an alteration of its by-laws bearing on the misconduct of Fellows and Members. We have already alluded to this feature of the work of the College in the past year. But for the opposition of a certain section of the Members the College might have had a still more powerful by-law. The incident shows how much stronger the College would be if it would meet the reasonable wishes of the Members for a modest representation on the Council. This demand cannot be long refused, and the sooner it is granted the more it will be appreciated. The concession of the just claim of representation would, we are convinced, add immensely to the strength of the College. Of all duties which the Council owes to the Members this is the greatest—to recognise their claim to a certain voice in the governing body. The College has set an example to all the medical authorities in making clear its own ethical powers by having them defined in a by-law that meets the approval of the Home Secretary. We call upon the other medical authorities to take note of this fact. But we look confidently to the Royal College of Surgeons of England for one example more for a due recognition of the claims of its own Members to a share in all the functions of the College. This step would initiate a harmony and a power in the profession hitherto wanting, and would secure for it the greater respect of statesmen and the public.

WE have already, in noticing the Report of the Sanitary Commissioner with the Government of India for 1893, touched upon a number of points that are embodied in the Report to Parliament on Sanitary Measures in India during 1893–94. But the number and importance of the subjects included in the Blue-book issued from the India Office a few months ago well entitle them to further consideration. Notwithstanding what has been said to the contrary, and in spite of the fact, as it seems to us, that Indian reports are too numerous and voluminous and too complicated and full of statistical tables to enable people to get at the information they really require, we hold that some of them are very ably compiled and valuable. It must be borne in mind that they are prepared for the information of Parliament and not for the special edification of the medical profession and *savants*; they deal with results and vital statistics, and not with scientific theories and hypotheses, except in so far as these have been made the basis of some legislative action and financial expenditure. The reports of the late Dr. BRYDEN, for example, quite apart from the correctness or otherwise of any generalisations or hypotheses he may have put forward, were in his day models of the way in which most valuable information could be condensed and rendered in tabular form. Instead of vague guesses about diseases and deaths in relation to climate, age, length of service, and many other points, they gave a foothold of facts and figures which enabled

Digitized by Google

the Government of India to calculate beforehand what they had to expect under given conditions and environments. This is, and must always be, one of the main objects of reports prepared for the information of official bureaux charged with the responsibility of practically forecasting the probable cost and results of political measures and departmental proposals. Nor are Government and other official reports invariably altogether devoid of scientific and literary interest. Some notice is generally taken of the prevailing view or doctrine of the day in relation to the facts and figures set forth. The report on the last census of India, to cite an example, was one of the most learned and interesting public documents that has ever been published. We have introduced these remarks with the object of pointing out that there is a point of view which is apt to be lost sight of—namely, the financial and administrative one—from which Blue-books must be regarded. We are far from saying that they are at any time a form of light literature, or that they are not capable of much improvement in the way of arrangement, clearness, and condensation, but they were not, it would seem, designed for the progress or elucidation of science or the diffusion of information regarding the results of modern scientific researches.

Turning, however, to the *précis* of the sanitary measures in India recently issued by the India Office we find that the health of the European army in India during 1893 was, on the whole, more satisfactory than in the previous year, save that there was a small increase in the daily sick-rate. The death-rate in an average strength of 70,091 was 12·61 per 1000; the loss by invaliding was 25 per 1000. Of the three armies in India that of Bengal was the most unhealthy. The chief causes of sickness in the whole European army were, as in the previous year, venereal diseases and ague. The chief cause of mortality was, as usual, enteric fever, which gave rise to 42 per cent. of the total deaths, or 5·29 per 1000 of the strength, as compared with a death-rate of only 0·04 per 1000 in the large native army. There were only sixteen admissions due to, and ten deaths from, cholera in the whole army in 1893. Among the general population cholera was also remarkably quiescent during 1893, the death-rate from this cause being the lowest recorded for some years, and showing a decrease of 507,188 on the deaths recorded from this disease in 1892. This fall was general almost all over India, and it forms a very striking and interesting fact. Under the head of "Fever" the deaths among the native population were enormous. The fevers were no doubt mainly of a malarious type; but there can be no doubt also that a very large number of deaths from other diseases are registered under this head. Brigade-Surgeon-Lieutenant-Colonel W. H. GREGG states that after an experience of twenty-two years spent in the study of the health of the people of Bengal he has no hesitation in saying that the crying want of the province is improved drainage, and that without it the death-rate from malarious fever will go on increasing. The Drainage Bill which is now before the Bengal Legislative Council he regards as being conceived in the truest and best interests of the people, and he adds a hope that nothing will prevent it from passing into law.

We may also add our hope that the Government of India will not lose sight of the scientific aspects of the problems that press for investigation in the medical history of a country, which affords an almost unique field for bacteriological researches. Mr. HANKIN'S labours in this respect have already been fruitful of results, and have given a precision to the various points that remain for further inquiry. We trust that bacteriological laboratories and scientific investigators will be multiplied in India and nothing be left undone to discover and remove the causes of such diseases as enteric fever, for example, which is so fatally prevalent among our young troops serving in that country. Recent views and researches have given a great impetus to the study of the causes of disease. Without a fairly accurate knowledge of what these really are it is scarcely necessary to say that our efforts to eradicate or diminish them must be futile. But all Government officials have probably a keen eye to practical results. The discovery of a specific bacillus as the essential cause of a disease is of great importance and scientific interest, but the matter does not end there, as if everything could be relegated to that discovery. The root of the matter lies in the practical outcome and application of such discoveries. What can an official do, and how is he to justify his action and the expenditure of public money to the men of culture and education, and of sound judgment perhaps, but with no special knowledge or technical training, with whom he has to deal? It is only fair to say that a great amount of work has been done and vast changes for the better have taken place in India, especially considering the poverty of the people and their aversion to all change or interference with their habits. Those who have had the best opportunities of knowing what the progress has been and the great difficulties which sanitary work in India has to contend against do not at all agree with the representations that have been lately put forward in this country; on the contrary, they regard them as unjust alike to the Indian Government and its medical services.

IT is not to be wondered at that the public have taken an intense interest in the issue of what has been called "the LANCHESTER case." At the South-Western Metropolitan Police-court on the 26th ult. Mr. SULLIVAN, a working man, who is described as a member of the Battersea Social Democratic Federation, asked Mr. CLUER, the magistrate, for his advice. He said that he was engaged to be married, and the ceremony was to have been performed that day, but the parents of the lady objected to the alliance because she did not intend to conform with the present marriage laws. In reply to the magistrate the applicant said that they were not to be married at a registry office, as they did not believe in the marriage laws as at present constituted; he added that he had been informed that the lady was forcibly removed to an asylum by her friends. The lady referred to is Miss EDITH LANCHESTER, who is twenty-four years of age and of good birth, position, and education. She is a well-known Socialist, and was a candidate at the recent School Board elections. It appears that she had been removed from the house where she was living upon a certificate of insanity granted by Dr. FIELDING BLANDFORD, who had been consulted by her father and brothers, who said they

Digitized by Google

thought she was not in her right mind. According to Dr. BLANDFORD'S statement, Miss LANCHESTER declared in his presence that she would live with Mr. SULLIVAN, that it was right to do so, and, in answer to a question, said she would not marry him even if he would marry her. She could give no reason for this conduct beyond saying that marriage was immoral. Dr. BLANDFORD states that he came to the conclusion that Miss LANCHESTER was of unsound mind for the following reasons: "I was informed that there was insanity in her family, her grandmother and an uncle having been insane; that she had always been eccentric, and had lately taken up with Socialists of the most advanced order. She seemed quite unable to see that the step she was about to take meant utter ruin. If she had said that she contemplated suicide a certificate could have been granted without question. I considered I was equally justified in signing one when she expressed her determination to commit this social suicide. She had a monomania on the subject of marriage, and I believed that her brain had been turned by Socialist meetings and writings, and that she was quite unfit to take care of herself." After a few days' detention in a private asylum Miss LANCHESTER was released upon the order of the Lunacy Commissioners who visited her and had an interview with her. Her opinions on the marriage question (she says) have undergone no change by her detention in the asylum; if anything, she holds to them more firmly than before.

This dramatic story has in it much of the serio-comic element. The man who wished to be married without marriage, and the woman who would not be married if she could form strange figures in our everyday real life; and they serve to illustrate the lengths to which ill-advised "morality" doctrines of the Socialistic type would impel young persons who are in other ways harmless and well meaning. On the other hand, the story brings us face to face with the question whether the persons thus indoctrinated are to be prevented from carrying out in practice the resulting social *modes* of their "morality" by authoritative restraint in asylums on the plea of insanity. The curious part of it is that we are unable to point to a player who is doing the part of "villain" in this tragi-comedy; for we believe that all the performers carried out their respective *rôles* with absolute *bona fides*, from the girl herself at the commencement to the Lunacy Commissioners at the finish. This fact, to our mind, simplifies the task of criticism and enables us to look calmly and deliberately at the main circumstance in the case after the first fervour of a needless public excitement has passed away.

When a man of Dr. BLANDFORD'S high position, great experience, and professional and personal uprightness gives his certificate of insanity, that certificate can be called in question only under circumstances of a very exceptional character. Looking at this case in all its bearings, we venture to regard the circumstances as, in themselves, almost unique; and if, therefore, in what is practically a test case, we feel that we are unable to agree with Dr. BLANDFORD as regards the necessity for the certification and immediate removal of Miss LANCHESTER to an asylum, it is largely due to the fact that we have had more time to consider the bearings of the question; while, on the other hand, we are bound to admit that we have not had, as Dr. BLANDFORD has had, the important advantage of completing our knowledge of the case by an interview with the young lady and of hearing her speak for herself. If any right-minded young lady of our acquaintance who had been carefully and religiously brought up were suddenly to proclaim the doctrine that marriage is immoral and to insist upon living with her father's coachman, we should have some difficulty in certifying her to be of sound mind. Indeed, we should naturally regard her as having "gone off her head" and should look for other indications of insanity; and, finding these, we should probably have her medically cared for and looked after. But when this doctrine represents the teaching, however preposterous, of a society or group of individuals, however insignificant, and when its logical outcome in practice brings up the question of the person's sanity for decision, as in Miss LANCHESTER'S case, we hold that a certificate of insanity and consequent removal to an asylum are not warranted or justified either on the ground of public safety or with a view to the earliest proper treatment of the mental condition. The point which Dr. BLANDFORD makes as to certification being equally justified whether the suicide determined upon is actual or merely social is not conclusive, because we have a right to use more forcible and extreme measures to prevent a person attempting to commit suicide, which is a criminal and punishable act, than we have to prevent a woman living unmarried with a man, however suicidal socially it may be for her to do so. If at the first blush of a case of this sort we might have been disposed to think with Dr. BLANDFORD that, so far as Miss LANCHESTER was concerned, the end justified the means, further reflection and the actual result show that the course pursued was not the best one, for the lady's mental state has not been improved, nor is it likely that prolonged and indefinite detention in an asylum would have altered her convictions. The far-reaching importance and relationships of optional and obligatory morality in regard to our individual and social life could not be more strongly evidenced than in this case; and we feel that medical men have a very heavy responsibility upon their shoulders in guiding unstable and eccentric members of the community through life successfully and without mishap. This responsibility becomes intensified in proportion as deviations from the normal in conduct stretch away towards positive insanity.

THE REPORT OF THE COMMITTEE ON PRISONS.—The annual report of the Howard Association, 5, Bishopsgate Without, E.C., contains some not altogether favourable criticism of the Report of the Committee on Prisons, full notices of which appeared in THE LANCET of May 4th, 18th, 25th, and June 15th, 1895. The association is especially opposed to the committee's recommendation that the isolation system should to some extent be relaxed. The committee were of opinion that the tread-wheel and other deterrent influences should be abolished, but in the absence of these it becomes the more necessary that cellular separation should be rigorously maintained. The committee, moreover, recommended associated labour, of course with due regard to classification. It is asserted, however, by some authorities that any associated labour, though apparently profitable in a financial sense, invariably results in the less hardened offenders becoming hopelessly deteriorated.

"Ne quid nimis."

FILTHY ICE-CREAMS.

THE report of THE LANCET Special Commission on the Sanitary Condition of the Italian Quarter, published nearly twenty years ago,[1] showed under what loathsome conditions ice-creams were made, and might have enabled any intelligent person to predict with certainty the exact species of organism which would be found probably in millions in a pennyworth of ice-cream on bacteriological examination. Is it, to take one example, at all surprising that the bacterium coli commune, the constant inhabitant of the human bowel and ever present in sewage matters, is found in ice-creams when we learn from our Commissioner's report that the mixture is made in filthy backyards or in dark cellars where it is exposed to foul emanations, gaseous, liquid, and solid, where the floor spaces oftentimes cannot be crossed except by boards, which in some instances sink suddenly into the sludge oozing from a defective drain beneath and splashing the malodorous mixture into any receptacle that may be near? We leave out the very questionable character of the materials employed in making ice-creams; they were bad enough, as our Commissioner saw, in some of the houses of the Italian quarter in London. Rotten eggs, bad flour, and repulsive-looking milk, all excellent pabula for the disease germ, are often, it is to be feared, the ingredients of the ice-cream compounder's recipe. The numbing effect of the ice upon the palate coupled with the sweetness of the sugar is an effectual disguise to the disagreeable taste of these ingredients. Bacteriological examinations of ice-creams have been made from time to time and more recently by Dr. Klein, whose report was discussed in THE LANCET of Oct. 13th, 1894. A fresh and a very exhaustive inquiry has just been completed by Dr. Macfadyen of the British Institute of Preventive Medicine and by Mr. Colwell, F.I.C., which should deal the death-blow to an evil unchecked and secure the prompt assistance of the Legislature to place these disease-breeding grounds under the control of the law. The average chemical composition of an ice-cream according to these investigators is as follows: total solids, 26·5 per cent.; fats, 4 per cent.; sugar, 12 per cent.; starch, 6 per cent.; albuminoids, 4 per cent.; and mineral matter, 0·5 per cent. Microscopical examination revealed the following delectables: bed bugs, bugs' legs, fleas, straw (bed?), human hair, cat's and dog's hairs, coal dust, woollen and linen fibre, tobacco, scales of epithelium, and muscular tissue. Could the list be more complete in absolute confirmation of our Commissioner's observations on the filthy environment under which they found ice-creams being made? ("The rooms contained as many double beds as could be got into them; there were no washstands, no basins, no towels—nothing but beds with very scanty, filthy, black bedding swarming with vermin."—*Vide* THE LANCET Commission, THE LANCET, Oct. 18th, 1879, page 590.) Shop samples were, as a rule, better as regards their bacterial contents than the street-barrow supplies, the maximum number of organisms found in the former being just over a million per cubic centimetre, and in the latter seven millions. The water used in making the creams teemed with micrococci, bacilli, and spirilla, one sample containing over five million bacteria in one cubic centimetre (about twenty-five drops). Putrefactive microbes were constant inhabitants, and so on *ad nauseam*. The results are too highly disgusting to need further comment, or to require at our hands any other remark on the urgent need for agitation for the immediate interference of public authority in this matter.

THE REMUNERATION OF MEDICAL WITNESSES AT ASSIZES AND SESSIONS.

IT will be remembered that early in the year a deputation from the United Kingdom Police Surgeons' Association waited upon Mr. Asquith, then Home Secretary. Their object was, *inter alia*, to show him how inadequately medical men were remunerated for their services as witnesses at all courts of law, but more especially when attending at assizes and sessions held in towns and cities distant from those in which they lived. It may also be remembered that Mr. Asquith courteously received the deputation, heard all they had to urge upon him with most exemplary patience, and conceded that the existing remuneration was not sufficient. But he frankly admitted that as his predecessors in office had declined to make any change, although their attention had been frequently called to the matter, he felt equally unwilling to burn his fingers. He suggested that in the case of police surgeons those bodies which appointed them should take the matter into consideration when fixing the salaries. This would still leave untouched the case of medical witnesses who are not police surgeons, and who comprise probably the larger proportion of medical witnesses. Moreover, the suggestion made by Mr. Asquith can hardly be regarded as either feasible or fair. Assize and sessions cases do not come with mathematical regularity, but in a very uncertain manner, and too often at the most inconvenient time. It would be impossible to fix such a salary as should fairly make up the deficiency of fees for attendance in such cases. Besides, it is obviously more just that the borough or county authorities who require the attendance of the medical witness should themselves remunerate him. It is the intention of the same Association to wait upon the present Home Secretary early in the ensuing year and to urge the importance of the matter upon him. The present autumn assizes will certainly furnish many cases illustrative of the hardship endured by medical witnesses, who so far from being remunerated are barely able to pay expenses while absent from home, and are not infrequently actually out of pocket. Full details of any such cases should be sent to the secretaries of the Association, Mr. F. W. Lowndes of Liverpool, and Mr. H. Culliford Hopkins of Bath.

SHOULD PATIENTS SMOKE?

DR. JANKAU, in an article in the *Zeitschrift für Krankenpflege*, tries to answer the question so often asked by patients and convalescents: "May I smoke, Doctor?" As a general rule there is no need to forbid the use of tobacco in surgical affections and during convalescence after operations, with the exception of those on the eyes, the abdomen, and the bladder. Does the use of tobacco play any part in the pathology of cancer of the lips and of the tongue? Nothing certain can be said on this point. It should be forbidden as a general rule in affections of the throat and of the pharynx, and with certain restrictions in catarrh of the naso-pharynx. The toxic action of tobacco must not be forgotten, and those suffering from internal affections should only be allowed to smoke with circumspection. Fortunately, however, most of the affections in which the use of tobacco is injurious are just those which cause the patient to dislike it; indeed, attention is often drawn to the fact that a man is unwell by his evincing a disinclination for smoking. Therefore, it is occasionally a good sign when the convalescent again feels a désire to smoke. Tobacco should be strictly forbidden in cases of peritonitis, typhlitis, and peri-typhlitis. According to Dr. Jankau gastric affections

Digitized by Google

should not be considered an absolute counter-indication. Patients who suffer from organic affections of the heart cannot generally tolerate tobacco with any ease; nevertheless, a habitual smoker may be allowed two or three mild cigars daily. As to pulmonary affections, experiments have taught us the prophylactic and even bactericidal action of tobacco on the micro-organisms of the mouth and those of carbuncle, of typhoid fever, and pneumonia. The same effect of tobacco is seen in the case of the bacilli of tuberculosis. He also considers that it is a great mistake not to allow those in the first stage of phthisis to smoke; on the contrary, he would encourage them to do so even more than formerly. There are two other points in favour of tobacco—its disinfecting qualities on the mouth and the soothing effect exercised by it on the genital functions, which at the beginning of tuberculosis are very excited. Moreover, tobacco has a favourable influence on the central nervous system, both on account of its slightly narcotic action and by distracting the patient's thoughts from himself and his illness to his smoking and the associations which it brings with it. It is most important that phthisical patients should be prevented from continually thinking of themselves and their malady. Tobacco need not be absolutely forbidden even when hæmoptysis exists, if only it is but slight. With regard to functional affections of the nervous system, it would not be advisable absolutely to forbid smoking from the commencement of the disease. The medical attendant should, however, be careful to state plainly the number and quality of cigars which may be smoked, and to ascertain as far as is possible whether the patient adheres to the directions given. In nervous affections of the heart it is most important that the greatest care should be exercised, and this is also the case with nervous dyspepsia. In fact, the use of cigarettes, however mild, may in the latter lead to very serious consequences. In organic affections of the nervous system great caution is requisite. Permission to recommence smoking during convalescence should only be accorded after a thorough examination, and the patient should be advised to act with great caution in this matter. In all cases both the quality and quantity of tobacco should be rigorously supervised and its consumption only allowed to increase gradually. He is very sceptical with regard to the so-called hypnotic property of tobacco; according to him this is nothing but a theory. Finally, he doubts the justice of the view held by the majority of people with regard to the good effects of cigars after meals. He advises that a small quantity of milk should be swallowed from time to time while smoking. This is especially desirable for patients or for those who are convalescent.

STREET NOISES.

THE Balloon Society have come down from the empyrean to the consideration of a very earthly and singularly annoying subject. At a recent meeting Mr. Charles Fox read a paper and laid a draft Bill before the meeting. This Bill, which we earnestly hope will pass, provides for the registration of itinerant musicians when British subjects, and their licensing when foreigners. There are other clauses dealing with the distance from any building within which playing should be allowed. Street music is bad enough, but an even more aggravating disturbance is caused by the hordes of howling sellers of newspapers. The halfpenny papers are the chief offenders, and if the Anti-Gambling League want to win popularity let them back up Mr. Fox's Bill, and insert a clause to the effect that anyone who yells "winner" in the street ought to be instantly arrested and his papers confiscated. On Sunday morning the noise is even worse than on a week-day, and the nuisance in certain parts of London is intolerable. We have not the slightest objection to Sunday papers per se, but no one should be allowed to cry them. Other noises made by costermongers, the sellers of coal, who moan like the old drivers of the plague carts, bands and the idiots who try to blow post horns on omnibuses, the Salvation Army and other itinerant preachers, demonstrations in aid of hospitals, and street collectors of all kinds should be rigorously put down. It is all very well to cant about the blessings of freedom, the birthright of every Englishman to earn his own living, and so on, but the freedom to earn one's living by annoying other people ought not to be allowed for an instant. In this matter the much-abused Russia is far more free than England. The traveller who walks through a Russian town is never pestered by newsboys, street collectors, or other plagues. The City is a portion of the metropolis comparatively free from nuisances of this description, and we cannot see why the rest of London should not be made equally quiet. We have referred to the subject upon previous occasions,[1] and shall continue to protest upon every opportunity, until freedom to annoy their fellow citizens is taken away from those who have the power to do so.

POISONING BY CREOLIN.

IN No. 41 of the *Deutsche Medicinische Wochenschrift* Dr. Pinner, physician to the Jewish Hospital in Hamburg, reports the case of a woman sixty years of age who had attempted suicide by swallowing seventy-five grammes of creolin. It was at first not known which of the preparations called creolin had been taken, but the druggist from whom it was purchased subsequently stated that he only sold Pearson's. The woman was found unconscious in her room and was taken to the hospital two hours after the attempt on her life. She was then comatose, with livid face, moist skin, and blue lips; her right pupil was larger than the left, and there was no reflex action of the cornea. Her temperature was 36·6° C., her pulse 112 and regular, and her respiration deep and snoring, with tracheal râles. In the pharynx there was a large quantity of white mucus; the palatal arches and the posterior wall of the palate were covered by a grey superficial coating. There was a strong smell of creolin in the breath. By the stomach-pump 300 grammes of a thick grey fluid mixed with mucus were withdrawn, and pressure on the pylorus caused thick brown drops of pure creolin to come through the tube. The first urine (150 grammes) was of a light-yellow colour, without albumin, sugar, or indican; the bromine-water test showed traces of tar acid in it. Microscopical examination revealed nothing abnormal. Milk given through an œsophageal tube was immediately vomited, but was eventually retained. An hour after admission into the hospital there were well-marked symptoms of shock, for which injections of ether were successfully made. There was also copious diarrhœa, and the stools had an odour of creolin. Some hours later the patient regained consciousness and afterwards became better. She complained of severe pain in the epigastric region and in the pharynx. The urine (80 grammes) was now of a dark-green colour, had an odour of creolin, and contained traces of albumin; by the tribromophenol reaction it was estimated that 7·5 c.c. of tar substances were present in 100 c.c. There was no hæmoglobinuria, and only a small quantity of leucocytes and red corpuscles and some casts. The patient slept very well during the first night, and on the following day there was an obvious improvement, the pulse, temperature, and respiration being normal, although she still complained of headache, want of appetite, and hoarseness, and an erosion on the epiglottis and the arytenoid

[1] THE LANCET, May 4th, June 8th, and Aug. 24th, 1895.

Digitized by Google

cartilage was observed with the laryngoscope. On the fourth day there was more diarrhœa, the stools still smelling of tar products. The urine continued for a week to be of a green colour and contained ½ per cent. of albumin, with much indican. After four weeks the patient was able to leave the hospital in perfect health and did not show any trace of injury from the poisoning. Dr. Pinner states that this is the seventh case of creolin poisoning described in medical literature, and that it was remarkable for the extremely severe symptoms which appeared almost immediately after the poison had been swallowed. Creolin, he says, used to be considered harmless because it could not be absorbed by the stomach, but in the above case the gastric juice very soon transmuted the creolin into a form which very quickly passed into the circulation and appeared after two hours in the urine. It was very remarkable that the urine of the first four days, even when kept in open glasses, showed neither any growth of bacteria nor any putrefaction, and the normal development of bacteria after exposure to the atmosphere occurred only in the urine passed on and after the fifth day. Dr. Pinner therefore suggests that the internal use of creolin may, perhaps, be useful in bacterial diseases of the genito-urinary system such as pyonephrosis, cystitis, &c. As it also checked fermentation in the bowels, perhaps intestinal derangements attended by extreme fermentation may be successfully treated by creolin. Notwithstanding the alarming symptoms of the first few hours, the patient very soon recovered, the creolin being obviously removed by the kidneys, which, though disordered for a short time, did not sustain any permanent injury. Creolin, therefore, according to Dr. Pinner, must be regarded as a comparatively innocuous substance. Another case of alleged creolin poisoning is reported by Dr. Gras of Vilshofen in the *Blätter für Gerichtliche Medicin*. A tuberculous woman thirty-five years of age was treated on the sixth day after confinement with vaginal irrigations of 3 per cent. creolin solution on account of fetid lochia. After the third irrigation the patient suddenly became collapsed and lost consciousness, the extremities being cold, the pulse feeble, and the respiration shallow; but injections of camphor and other restoratives were very soon followed by recovery, and no traces of carbolic acid were found in the urine. It seems rather doubtful whether these symptoms were due to creolin poisoning or were merely the effects of shock occurring in a woman weakened by childbirth and tuberculosis. There were no positive toxic symptoms, and the quick recovery makes it probable that the seizure was not really due to poisoning.

TRADES AND THE WEATHER.

EVERYONE will remember *Mr. Punch's* picture of the depressed sandbag vendor on a warm day. "No trade?" "No. Lord send us a real crool east wind, that's wot we wants." Another trade, somewhat more aristocratic than the one we have referred to, insomuch as it trenches upon the medical profession, is the cough-drop trade, and it, too, is dependent upon weather, being "quiet" when fine and "booming" in a "Kaffir"-like manner (we like the strictly commercial style) when good foggy weather comes. Such were the arguments put forward by a Mr. Hemming summoned for not paying his gas bill; the weather had been fine, trade had been bad, consequently he could not pay. The cough-drop of the summer, it appears, gives place to the "paregoric tablet" of the winter, cough-drop apparently being too familiar an expression to impress the average buyer. Among a certain class it is used as a term of affection or opprobrium, we are not certain which—e.g., "the Battersea cough-drop," as a certain M.P. was called the other day. Paregoric tablets, we presume, have a small quantity of opium in them, and it is to be hoped that mothers will not give babies too many of them, for the corner of the handkerchief through which the delicacy is sucked, though it keeps out the dust which has settled on the tablet from the street, will not keep out the opium.

PROSECUTION OF A MIDWIFE.

WE learn that the Superintendent Registrar of Merthyr Tydfil recently summoned a midwife for making a false statement as to the birth of a child. She had declared that it was stillborn, but medical and other witnesses proved that it had lived for some hours and that death resulted from suffocation. She was found guilty and fined £2 10*s*., with the alternative of a month's imprisonment. In the course of the proceedings it was mentioned that the coroner had informed the Registrar-General that, in his opinion, offences of this description were not uncommon in the district. An almost precisely similar case which occurred in Battersea was recorded in THE LANCET of Dec. 1st and Dec. 8th, 1894, and the prosecution initiated by the coroner resulted in the infliction of a fine. It is satisfactory to find that the authorities are prompt to use all the means in their power for the repression of this offence, which is so full of peril for infant life, and the commission of which is so much facilitated by the non-registration of still-births.

PARACENTESIS OF THE SPINAL THECA.

PROFESSOR QUINCKE of Kiel was the first to advocate and practise puncture of the spinal sheath in cases of cerebro-spinal meningitis, whether tuberculous in origin or not. This simple expedient has, however, not been much practised elsewhere, and in many cases has not been followed by permanent results. It is obvious that if it is to be of use in tuberculous meningitis the case must be one in which no other region or organ is the seat of miliary tubercle, and that may explain the fact of failure to ensure recovery even after a marked improvement as regards the cerebral symptoms, such as disappearance of coma, has followed the lumbar puncture and drainage. In a paper read before the recent meeting of the Association of German Naturalists and Medical Men (*vide* THE LANCET, Oct. 19th, 1895) Professor Quincke laid stress on its value in diagnosis. He affixes a manometer to the trocar and thus measures the degree of pressure within the canal. Failure to secure a flow of fluid is to be attributed to imperfect performance of the puncture—e.g., the passage of the needle between the nerve roots outside the sheath, or the presence of thick pus which will not flow through a too fine needle. He is convinced of the therapeutic value of the plan, especially in rapidly developing forms of acute serous and sero-purulent meningitis. Professor Quincke announced that one of his assistants was preparing an account of the experiences of his clinic on the method for publication in the *Archiv für Klinische Medicin*. Professor von Ziemssen said that there has been ample confirmation of the reports as to the diagnostic and therapeutic value of the lumbar puncture since its introduction by Professor Quincke. He himself had injected a weak solution of iodine into the canal by this means. He did not use a trocar, but a simple Dieulafoy's needle. Sometimes the patient, shrinking at the moment of puncture, approximated the vertebræ and thus hindered the entrance of the needle, and he thought that anæsthetics should be given in the case of adults. No reaction followed, and in some cases examined after death no trace of the puncture could be found. In acute cerebro-spinal meningitis, which occurred sporadically in Munich, he had seen good result, as well as in serous spinal meningitis. It was surprising that in uræmia, in spite of the high arterial pressure, only

Digitized by Google

a few drops of fluid are to be found in the cerebro-spinal sac. Dr. Lenhartz had done lumbar puncture in fifteen cases, of which three were cerebro-spinal meningitis. In several cases there was no result, although the needle undoubtedly entered the vertebral canal. In one case, ending fatally after two days, 80 c.cm. of slightly sanguineous fluid escaped. The puncture was without any effect in this case on consciousness, pulse-rate, &c. Only once had he found tubercle bacilli in the fluid, and in another case the tuberculous nature was proved by inoculation experiments. In one instance, after the escape of 100 c.cm., the patient grew worse. Professor von Ziemssen said that in severe cases the patients will always die. Exceptions cannot disprove the rule. In many cases the favourable course was certainly to be ascribed to the puncture.

CHOLERAIC AND DIARRHŒAL FATALITY IN GRIMSBY.

SOME time back the corporation of Grimsby complained somewhat bitterly of announcements of deaths in connexion with cholera in their borough. We are well aware of the fact that the term cholera as used by the Registrar-General in his quarterly returns does not necessarily imply Asiatic cholera; but when we look at the deaths which occurred in the Grimsby sub-district—which, in addition to Great Grimsby, includes Cleethorpes and some rural area—we find enough to justify the gravest apprehension as to what has been going on there. In the quarter ending Sept. 30th last 124 deaths were registered from diarrhœa, 22 from "cholera," and 10 from "fever." These are the headings of the Registrar-General's return. They indicate a very grave loss of life and call for some public explanation as to what this serious fatality was due to, and also whether the causes of it were exceptional and temporary or whether they are permanent.

PRACTICAL DISINFECTION OF ROOMS.

THE frequency with which second and third cases of scarlet fever appear in houses that have been disinfected by the inspectors of sanitary authorities casts grave doubts on the efficiency of the procedure usually adopted, despite its official sanction. Stripping the walls, lime-washing walls and ceilings, and scrubbing wood-work and floor-boards with soap and water are indeed effectual enough, and to these when thoroughly done we are disposed to ascribe any successful results rather than to the more technical process of so-called disinfection by sulphur fumes, which is little better than a superstitious rite or incantation shorn of the religious character it had in the mind of Ulysses when he "fumigated" the halls desecrated by the massacre of his wife's suitors after removing the corpses and washing away the blood with a promptness that precluded all thought of other than moral pollution. But in the light of bacteriological experiments dry sulphurous acid fumes, whether generated by burning sulphur or carbonic sulphide, or, as has of late become the fashion, by opening cylinders of the compressed gas, are for all practical purposes useless. The gas would act as a fairly powerful germicide on articles or fabrics previously saturated with water, but its bleaching action precludes its employment in this way with coloured materials, carpets, or curtains, and it is as what is called an "aerial disinfectant" that it holds its ground in popular esteem. But aerial disinfection is an absurdity; no one wants to purify the foul air, which is easily enough removed by simple ventilation. In disinfecting a room the true aim is to kill the germs contained in the dust on ledges or in the crevices between the boards, or adhering to the walls and other surfaces, and the dry gas is powerless for this, which is best attained by a sublimate solution of the strength of 1 part in 1000, or by lime (not white) washing, provided the lime be fresh burnt and caustic; the carbonate or chalk used in white washing under the name of whiting, and into which lime is converted by long exposure to the air, being inert. The series of experiments on the infection and disinfection by various means of wall papers, distempers, and other wall surfaces conducted by Dr. Cronberg, under the direction of the late Professor Uffelmann at Rostock, showed that subsequent scrapings were invariably and almost instantaneously sterilised by washing or spraying with the sublimate solution and equally so by lime-wash after the lapse of twelve to twenty-four hours. The danger of corrosive sublimate is, we believe, exaggerated, for the smallest fatal dose for an adult being probably three to five grains—equal to at least a quarter of a pint of the solution—accidental poisoning with the solution is practically not probable, and as a further safeguard it might be coloured with indigo or "laundry blue." Carbolic acid, which is sold without restraint and is in universal use, is more dangerous on this account, and is, indeed, frequently employed with suicidal intent and with fatal effects. In France, Germany, and Italy sublimate has nearly superseded all other disinfectants, and its neglect in this country is inexplicable. As to carpets, curtains, bedding, and clothing, all that is capable of being washed should be plunged in a copper of boiling water for a quarter of an hour and such articles as would be spoiled by this treatment should be disinfected by steam.

COLD BATH TREATMENT OF TYPHOID FEVER.

THE treatment of typhoid fever by the cold bath method has been written on over and over again. It has been proved to be a most valuable one in many cases, and consequently just comments and further record of cases should be duly welcomed and considered. In the *Philadelphia Medical News* of Oct. 12th, 1895, a paper on the subject appears by Dr. Osler, giving his five years' experience with the cold bath treatment of typhoid fever. He states that during the first year of the hospital service typhoid fever was treated symptomatically. The number of severe cases admitted was unusually large, and there were eight deaths among thirty-three patients—a percentage of 24·2. For the past five years ending May 15th, 1895, systematic hydro-therapy had been used—the method of Brand, with certain minor modifications. Each patient received a tub bath of twenty minutes at 70° F. every third hour when the rectal temperature was at or above 102·5°. Frictions were applied in the bath, and a warm drink or stimulant given afterwards. The following are the general statistics given by Dr. Osler:—Cases admitted during the six years ending May 15th, 1895, 389; number of deaths, 34; percentage of mortality, 8·7. Cases admitted before the introduction of hydro-therapy, 33; number of deaths, 8; percentage of mortality, 24·2. Cases admitted since the introduction of hydro-therapy, 356; number of deaths, 26; percentage of mortality, 7·3. Number of cases bathed, 299; number of deaths among the bathed cases, 20; percentage of mortality in the bathed cases, 6·6. The percentage 7·3 represents the total mortality during the past five years, but as it does not represent the true mortality of the cases treated by hydro-therapy the figures must undergo a further analysis. Many circumstances interfere with the systematic carrying out of the plan which Dr. Osler pretty fully criticises. We have not space to give more than the smallest sketch of his remarks, but the original paper will well repay perusal. In the first place, a number of cases are admitted in the second or third week with a falling temperature; such cases are not bathed. In the very mild cases, also, seen more frequently in private than in hospital service, the baths are unnecessary. In the second place, some patients are admitted late in the disease and are too ill to be bathed. Thirdly, there is a group of cases

he
while, on

Digitized by Google

which present serious complications—hæmorrhage, signs of perforation, very intense bronchitis, pneumonia, pleurisy, or intense meteorism, with severe diarrhœa. Fourthly, there are cases which are not bathed at first because the diagnosis seems doubtful. Two of the fatal cases fell into this group. Two advantages are claimed for hydro-therapy in typhoid fever—a mitigation of the general symptoms of the disease and a reduction in the mortality. From his experience Dr. Osler is of opinion that these claims are well based. He maintains that the cold bath treatment, rigidly enforced, appears to save from six to eight in each hundred patients suffering from typhoid fever admitted to the care of the hospital physician.

MEDICAL EMERGENCIES IN THE NIGHT.

How long will it be before society makes provision for the night emergencies of illness as it does for those of fire? At present it throws all the onus on the medical profession, and medical men are expected to turn out at any ring of the bell, perhaps when themselves ill or exhausted after a hard and ill-paid day's work. The *Bradford Observer* publishes the particulars of such a case. A labourer attacked in the night with hæmatemesis sent for two or three medical men, who exercised their right of refusal. At last his messenger met a policeman, who sent him to the relieving officer, who gave him an order to Mr. White. When Mr. White's assistant arrived about an hour and a half later—he would have been there sooner but for some misreading of the address—the patient was dead. The jury was satisfied with the assistant's (Mr. Burnett's) explanation, and returned a verdict of "Death from natural causes." The question of emergencies and the provision for them remains. It is unreasonable to throw the blame of non-attendance on medical men. *Semper paratus* is an excellent motto for the profession, and one generally acted on, but it implies some obligation on the part of society. And the reckless carelessness of society in the matter is to blame for instances in which the usual benevolence of the profession seems to fail.

LEPROSY IN NEW SOUTH WALES.

THE total number of persons admitted to the New South Wales leper lazaret at Little Bay from April 19th, 1883, to Dec. 31st, 1893, was fifty, six of whom were females, all of European descent, five being natives of New South Wales and one a native of New Zealand. Of the forty-four males nine were natives of New South Wales, all of European descent, and one was English, the remainder being made up of twenty-nine Chinese, one native of India, one West Indian, one Javanese, and two South Sea Islanders. During that period there were thirteen deaths, and the West Indian patient was discharged, his sores having healed and there being no law warranting his detention. On Jan. 1st, 1894, there were, therefore, thirty-six persons at the lazaret. During 1894 twelve persons were reported in accordance with the Leprosy Act as suspected lepers, but on investigation seven were found to be suffering from some other disease, and five who suffered from leprosy were placed in the lazaret; of these one was a native of New South Wales, of European descent, one a native of Queensland, of European descent, one a native of Saxony, one of New Caledonia, and one of India. The number remaining on Dec. 31st, 1894, was forty, one native of New South Wales having died during the year. The number of persons segregated during 1894 is considerably less than during any year since the notification of leprosy became compulsory; the comparatively numerous admissions during 1891 and 1892 were no doubt owing to the newly created necessity of notifying cases. No application has been made to the Board of Health for the special isolation of any patient outside the lazaret, and at the present time all known cases of leprosy are confined there. The accounts contain entries of £148 for drugs and £168 for tobacco, cigars, and opium. The attendants and nurses at the lazaret are under the direct supervision of the medical superintendent and the matron of the Coast Hospital. Elaborate descriptions of the last five cases, written by Dr. J. Ashburton Thompson, have been printed by the Board of Health Office, 127, Macquarie-street, Sydney, and every facility is given to members of the medical profession to visit the lazaret for the purpose of studying the disease.

THE CASE OF SURGEON LEA.

WE have referred to this case upon several previous occasions.[1] We understand that several members of Parliament have interested themselves in the question and that the subject will, doubtless, be referred to on the reassembling of Parliament. We notice that the *Times* of Nov. 6th in its Naval and Military Intelligence contains the following announcement: "Captain W. L. H. Browne to the *Ringarooma*," and we shall be curious to see whether this has any bearing or not on the matter in question.

"SUMMER AND WINTER WITHIN A MONTH."

OUR chief rainfall authority, Mr. G. J. Symons, F.R.S., writing to our contemporary the *Times*, gives under the above heading some interesting figures with regard to the temperatures in London during the last seven days of September and the corresponding dates of October. The mean of the maxima and minima in September from the 24th to the 30th was 65·0°, 1·9° warmer than the average warmest week during a long series of years. The mean of the maxima and minima in October during the period referred to was 35·9°; the average temperature of the coldest week, also during a long period of years, is 37·9°, thus making the week ending Oct. 30th, 1895, 2·0° colder than the average coldest week in the year. The occurrence of second fruit crops and spring blossoms in winter comes upon us now with little or no surprise, but the above facts are little less than sensational.

THE GASEOUS PRODUCTS OF CERTAIN PYRENEAN WATERS.

IN some of the sulphurous springs in the Pyrenees the water is remarkable for producing very minute gaseous bubbles soon after it is drawn, the ebullition in a few instances continuing for hours. Many of these springs, which are called *azoades* by the Spaniards because they yield nitrogen, are to be found on the southern slopes of the range, at Panticosa, and elsewhere; but, as is well known, there are also several on the French side, the most celebrated being those of Salut de Bigorre, Cauterets, and La Rallière. During a sojourn at Cauterets MM. Bouchard and Troost occupied their leisure in analysing these gases, and the following are the conclusions which they communicated to the Académie des Sciences: "We are not absolutely decided as to the origin of all the gases contained in these mineral waters, and it is possible that those with which we occupied ourselves may have owed their origin to the atmospheric air drawn down into the depths by the surface water. The latter, after undergoing alkalinisation in a sulphurous medium, would rise again to the upper stratum, deprived necessarily of oxygen and carbonic acid, and containing only nitrogen and argon. It would seem, nevertheless, even at this stage of the investigation, that although a portion of the argon, and perhaps also of the helion, may be derived from atmospheric sources, the presence of both is likewise due in part to some subterranean action. In one of

[1] THE LANCET, June 15th, 22nd, and 29th, and Aug. 17th, 1895.

Digitized by Google

the springs which we examined both these gases were found coexistent, whereas in another helion alone was revealed, while in a third there was evidence of something in addition to the helion, which was certainly not argon." In this connexion it would be interesting to note whether any correspondence exists between the medicinal properties of the various Pyrenean waters and the nature of the gases emanating from them, more especially with reference to argon and helion. The entire subject is well worthy of renewed investigation, when no doubt many other important points will receive elucidation.

METROPOLITAN HOSPITAL SUNDAY FUND: COUNCIL MEETING.

A SPECIAL MEETING of the council of the Hospital Sunday Fund was held on Thursday last, Nov. 7th, under the presidency of Sir Joseph Renals, Bart., the retiring Lord Mayor, to receive the report of the Distribution Committee, who at their meeting last week announced that the sum of over £61,000 would be available this year for distribution among the various hospitals. At the same time it was hinted that a still further sum would probably be forthcoming before the financial year of the Fund closed. This means that participating institutions will receive a further grant equal in amount to three-eighths of the grant made in August last. The receipts from the churches this year exceed those of previous years, but it must be borne in mind that it is to the munificence of Mr. Barnato and his friends that the increase is in a great measure due. The Lord Mayor, too, has worked most assiduously for the Fund, and as he now gives place to his successor as President of the Fund we take the opportunity of tendering him our most hearty thanks, not only for his kindness in placing the rooms of the Mansion House at the disposal of the Fund, but for his personal labours in presiding at the meetings and his ever-ready help and interest in all that concerned the Fund. A full report of the proceedings will appear in our next issue.

THE ADMINISTRATION OF OATHS IN COURTS OF LAW.

OUR remarks in THE LANCET of Oct. 26th on the above subject have this week received an endorsement in a Sussex police-court which it is hard to look upon as other than a very unwieldy and ridiculous joke. The Rector of Graffham and East Lavington, the Rev. Rowley Lascelles, was concerned as a witness in a trespass case which was heard recently before the Petworth magistrates, Major Sir Walter G. Barttelot, Bart., being in the chair. Mr. Lascelles asked to be sworn in the Scotch fashion, whereupon the following colloquy ensued:—

The Chairman: I should like to know, Mr. Lascelles, why you, being a clergyman of the Church of England, object to kiss the Book?
The Rev. R. Lascelles: I have a strong objection to kissing the Book in these days of infectious diseases. I should be happy to kiss it if I may turn it inside out.

This was done, and Mr. Lascelles having been sworn in the usual fashion the chairman went out of his way to remark in an undertone: "He is afraid of catching an infectious disease from the Bible." Would Sir Walter Barttelot argue, then, that scarlet fever could not be caught at church, and that while a patient's letters and novels would need disinfecting, contagion could not be conveyed within the pages of his Bible or Prayer Book? Even more to be deprecated was the speech of a later witness, who, when he was sworn, piously remarked: "Although I am only a layman I am not afraid of catching infectious diseases from the word of God." It is impossible to believe that these phrases were the result of any thought whatever. If certain combinations of words and letters are safeguards against contagion, let us drop isolation and return to the use of phylacteries; let us inscribe the walls of our small-pox hospitals with pious phrases and build Board schools next door, for absurdity such as this would be our justification.

CANCER CURERS IN SWANSEA.

A SWANSEA correspondent writes that Mr. E. Davies, the medical officer of health, and Messrs. Rawlings and Brook attended last week at the police-court and complained to the stipendiary magistrate that a number of persons in Swansea profess to be able to cure cancer, and although not possessed of any medical knowledge or qualifications, nevertheless give advice to patients suffering from this disease. Cases were adduced in proof of these statements, and a summons was applied for against one of these pretenders, a woman who had treated a patient improperly. The stipendiary magistrate regretted the facts, but said that he was unable to take any action in the matter, and thought that some amending of the Medical Acts was required. Cancer patients in their emergency lend a willing ear to the specious promises of ignorant or interested advisers. Legislative enactments against the abuses connected with unqualified practice would no doubt be desirable, but in the present state of public opinion there is little hope of their being seriously considered, and such social anomalies as the cancer curers in Swansea, provided that they make no claim to the possession of a diploma, usually incur no penalty or reproach beyond the occasional censure of a coroner's jury.

THE TYNE PORT AND THEIR MEDICAL OFFICER.

THE announcement made in our columns on Oct. 26th (p. 1074) that Dr. Henry Armstrong had resigned the post of medical officer of health to the Tyne port sanitary authority will have been received with regret; but it is impossible to regard his action otherwise than justified under the circumstances. The trivial attempt made a short time ago to identify him personally with a case of small-pox that occurred in one of the Tyneside districts showed that on his board there were some at least who failed altogether to appreciate the high professional standing which Dr. Armstrong has acquired in matters relating to public health during a series of years which he has devoted to that subject. And no one could have been surprised, when application was made to the Local Government Board to inquire into the matter, to find that the central authority informed the port authority, after fully considering the matter, that they saw nothing whatever to inquire into. This rebuff was followed by a motion that was desirable that the port medical officer should live near the mouth of the river, and Dr. Armstrong at once wrote a dignified letter to the authority stating that he could conceive that the alteration thus suggested might have certain advantages, and therefore, in order that the authority might feel perfectly free to act as they saw best, he placed his resignation in their hands. Now the port authority want to get another officer for £150 a year—that is, we presume, someone who will either work up a respectable means of living by taking other work elsewhere, or someone already busily engaged in private practice in the neighbourhood. But they evidently see that to lose the services of an official who has devoted his whole time to his public duties will be a blunder, and hence they want to retain Dr. Armstrong as a consulting officer. Whether he will ever accept any such divided responsibility towards a body which has acted as the Tyne port authority

Digitized by Google

has remains to be seen. One thing is certain, the notoriety for successful action which attaches to this port is due to the notoriety for ability and administrative capacity which in this country—and, indeed, in Europe and America—has been acquired by Dr. Armstrong as one of the leaders and pioneers in the work of port sanitation. It was his individuality that gave such confidence during the cholera importations of 1893-95; and his loss will be a loss to a larger circle than the authorities whose districts border on the Tyne.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL SERVICES IN INDIA.

WE have been favoured with a copy of a resolution and protest from the South Indian Branch of the British Medical Association, relative to the proceedings and action taken by the Public Health Section of the association at its late meeting in London, for publication in THE LANCET. The resolution has reference to the subject of Indian sanitation, and was adopted at a special meeting held at Madras on Sept. 20th, and has been forwarded to this country with the view of its being laid before the council of the association. We have already dealt with this subject generally in an Annotation in THE LANCET of Oct. 12th last in connexion with the communications which we had received thereon from various other sources. The matter having now been referred to the council of the British Medical Association, it does not seem necessary to publish the documents *in extenso* in our pages. Briefly described, the resolution with its accompanying protest refers in strong terms to the alleged inaccurate, misleading, and unjust nature of the statements that have been put forward, and upon the unmerited discredit which such statements are calculated to bring upon a large body of the profession in India and upon the Government which the medical officers in both the civil and military departments have the honour to serve. It is contended that an accurate knowledge of all the facts regarding sanitary progress in India, and of the work done there during the past thirty years by members of the medical services and of the medical profession generally, would lead to a very different conclusion from that which seems to have been formed.

AFTER full consideration it has been determined to hold the meeting of the General Medical Council at the usual time. Members have been summoned to meet on Tuesday, Nov. 26th, at 2 P.M. The meeting will be held at the Royal College of Physicians of London. This is not the first time the Council has been indebted to the kindness of the College. We cannot but think that the President is acting wisely in holding the usual meeting, even if at some little inconvenience to the members and officials. The powers of the Council are too grave for a few months' delay to make no difference. The meetings of committees will be held as usual at the premises in Oxford-street.

WE beg to call the attention of our readers to Sir William Broadbent's letter (p. 1187) urging upon the profession the claims of the British Medical Benevolent Fund. The work which the Fund does is admirable, and the distress which it relieves so genuine and so bitter, that we feel confident that the honorary treasurer's appeal will meet with cordial replies.

PROFESSOR H. MARSHALL WARD, F.R.S., the well-known cryptogamic and physiological botanist and Professor of Botany in the Royal Indian Engineering College, Cooper's Hill, has been elected Professor of Botany in the University of Cambridge, in the room of the late Professor Babington.

THE BATTLE OF THE CLUBS.

(Continued from p. 1137.)

THE FORMATION OF A PROVIDENT MEDICAL ASSOCIATION AT BEXHILL-ON-SEA.

WE congratulate the medical men of this seaside town on the formation of a Provident Medical Association on the lines of the combination whose success is already assured at the neighbouring town of Eastbourne. The following are the rules and constitution of the Bexhill Provident Medical Association formed in October, 1895:—

RULES AND CONSTITUTION.

1. *Object.*

This Association is a self-supporting society to enable those who cannot pay for medical attendance at the usual charges to secure for themselves and their families the advantage of medical attendance, advice, and medicine during illness.

2. *Management.*

It shall be managed by a general committee, which shall consist of the whole of the medical men in Bexhill who shall sign the undertaking. The general committee shall appoint a chairman and honorary secretary annually. The whole of the business of the Association shall be managed by the general committee, which shall hold an annual meeting and, in addition, shall meet as often as the business of the Association demands. Four members shall form a quorum.

3 *Undertaking.*

Any duly qualified and registered practitioner residing in Bexhill (not practising as a homœopath) may become a member of the staff subject only to his appointment being approved by the committee. All members of the staff must also sign an undertaking—1. Not to conduct clubs of their own at all (other than friendly societies registered under the Act) unless it be at rates the same or higher than those of the Bexhill Provident Medical Association. 2. To have no professional intercourse whatever with any medical man who associates himself with any of the companies known as medical aid societies or with similar institutions so long as the methods adopted by these societies include (*a*) canvassing for members in the interests of individual practitioners, (*b*) the virtual sweating of their medical officers by the inadequate remuneration offered for the work done.

4. *Membership.*

Artisans and their families, and others who may be considered suitable by the committee shall be eligible for membership, provided they live within two miles and a half from the town hall. No person can become a member who is in receipt of parochial relief. All applicants must be in good health on joining, and must first be passed as such by one of the medical officers. If persons in indifferent health are to be admitted at all it can only be at special rates determined by the committee. Each medical officer shall receive the subscriptions from the members on his list, and render to the monthly meeting a list of defaulters and new members.

5. *Wage Limit.*

Although a most desirable matter, it is very difficult in practice to adopt a hard-and-fast "wage limit," and therefore it would appear that the best way of preventing abuse of the Association by persons who are too comfortably off will be by leaving absolute discretion in the hands of the committee to consider the case of every applicant on its own merit. But, as a general rule, it may be laid down that in the case of families they shall be eligible, if the combined incomes of the parents do not exceed 30*s.* a week, at the rate of 2*d.* a week each adult—*i.e.*, over fourteen years of age—and 1*d.* a week for each child. It will be expected that the whole of the family shall be entered on the lists (exception being made in the case of any members who may be already members of a registered friendly society), but in large families not more than six children shall be charged for. Any person who has been a member in childhood can, on completing his or her fourteenth year, continue as an adult member by paying the additional penny a week.

No domestic servant can be admitted as a *joining* member, but a member who enters service does not thereby forfeit the privileges of membership. When in service servants can only be attended at the surgery. Single persons shall pay at the rate of 2*d.* a week.

If at any time a member is discovered to be in receipt of an income such as renders him or her, in the opinion of the committee, unsuitable for membership, it shall be in the power of the committee to remove his or her name from the books of the Association on giving such member a quarter's notice. But it shall always be open to such persons to first explain their circumstances to the committee if they so wish. Each member or family shall have a card of membership bearing their names and address; and on the back of this card receipts of all payments shall be made by the doctor on whose list the members are. To cover the cost of printing and material a charge of 2*d.* will be made for each card.

All the subscriptions are to be paid monthly or quarterly, and in advance, to the member's medical attendant. No member more than a month in arrears will be entitled to the benefits of the Association. If any member be more than two months in arrears his or her name shall be erased from the books. No person who, having been erased from the books, desires readmission shall be received again as a member unless he pay up all arrears due by him or such part of the same as the committee may require.

Members on joining must select their own doctor, but cannot change him for another without first informing him verbally or in writing that it is their wish to place themselves under another member of the staff; and they must always give a quarter's notice of any such change.

Each of the medical staff shall have the right to refuse to receive on his list any member.

In the event of a married member expecting to be confined, it will

Digitized by Google

be expected that she shall employ the doctor on whose list she is to attend her. If she does not, she will forfeit her right to his professional services for a period of six weeks from the date of her confinement. The fee for attendance at a confinement is 15s, and must be prepaid to the doctor in full one month prior to the confinement. Attendance at a miscarriage or premature confinement will be at the same rate. The fee for vaccination shall be 2s. 6d. Fractures, dislocations, and major surgical operations will be charged for at the following rates:—

Nature of Case.	Charge. £ s. d.
Compound fracture of thigh or leg ... ... Amputation of leg, arm, foot, or hand ... ... Strangulated hernia	5 0 0
Fracture of lower jaw ... ... Simple fracture of thigh ... ... Simple dislocation of hip ... ... Fracture of patella	3 0 0
Fracture of leg, tarsus, metatarsus, or toe ... ... Amputation of finger or toe ... ... Dislocation or fracture of arm or forearm ... ... Dislocation of knee or ankle ... ... Fracture of carpus, metacarpus, fingers, or thumbs ... Fracture of clavicle, scapula, olecranon, or ribs	1 0 0

A minimum fee of 10s. 6d. shall be fixed for consultations or assistance at confinements.

All the above rules and any others they may subsequently adopt the committee shall have in their power to alter, provided there is a two-thirds majority of the committee in favour of the proposed change, and provided also that every member of the committee shall have had twenty-eight days' notice of the meeting and have been informed at the same time of the terms of the resolution to be laid before the meeting embodying the proposed alteration.

We are gratified to learn that the formation of the association had its origin in the articles published in THE LANCET. For it is honourable and amicable coöperation of this kind that will alone protect the members of the profession against the tactics of some of the numerous sick aid institutions whose methods include—in the words of the above memorandum—(*a*) canvassing for members in the interests of individual practitioners, and (*b*) the virtual sweating of their medical officers by the indequate remuneration for the work done. The rules of the Bexhill Provident Medical Association strike us as being good and comprehensive, and we recommend them to the consideration of medical men in other quarters where a stand against organised oppression is felt to be necessary. The committee of management consists entirely of the medical men who do the work, and no place is found upon it for the sort of philanthropist whose name too frequently figures on the bills of charitable institutions where the only thing to be given away is the medical man's time and labour. The unanimity of the local practitioners in the promotion of such associations is, of course, the essence of their success. Indeed, it makes the success inevitable; and that this has been already recognised at Bexhill is proved by the fact that an emissary from one of the sick-aid institutions has been to the town with a view of persuading some one of the medical men to default. We are happy to learn that he was quite unsuccessful. The poor of Bexhill who are unable to pay for medical attendances at the usual charges will be able to secure for themselves direct from their medical men adequate attendance at rates which will allow of the proper discharge of the duties undertaken; while their just claim to such consideration will not be vitiated and obscured by the intrusion into the provident association of persons quite able to pay on a higher scale. The poor will be benefited and the medical men will manage their own affairs instead of being placed in the position of underpaid employés.

RIVIERA WINTER SERVICE.—The International Sleeping Car Company announce the following arrangements for the winter season in the South of France:—The Calais-Mediterranean Express will run every Thursday (commencing Nov. 7th) in connexion with the 9 A.M. service from London (Victoria and Charing-cross), calling at Marseilles, Cannes, Nice, Monte Carlo, Mentone, &c., reaching Vintimille at 12.36 P.M. the following day. Baggage will be registered through to destination and examined *en route*. The train will be composed entirely of the company's sleeping and dining cars. A Mediterranean Express will also leave Paris (P.L.M. station) every Tuesday and Saturday at 5.30 P.M., reaching Vintimille at the same time as Thursday's train from Calais. The Nice Express will leave Paris (Gare du Nord) at 7.44 P.M. daily, to which, between the Nord and Lyon stations, a restaurant car will be attached. The Rapide will leave Paris (Gare de Lyon) for the Riviera every evening at 8.25. Through tickets, single and return, are to be obtained at the company's offices, at 14, Cockspur-street, S.W., where places must be reserved in advance.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

THE NEWPORT EPIDEMIC OF 1894.

THE official report[1] by Dr. Theodore Thomson on the serious epidemic of enteric fever which occurred at Newport, in the Isle of Wight, in the autumn of last year has been issued by the Medical Department of the Local Government Board. It is a somewhat voluminous document and it contains a number of lithographed and other plates; but having regard to the importance of the occurrence from a public health point of view, especially in relation to chalk waters, it is much to be regretted that the Stationery Office should place a price on it which is so high as to carry the suspicion that they want, on behalf of the State, to make money out of it. Including some 40 attacks of enteric fever in the earlier parts of 1894, there occurred no less than 436 attacks of that disease on a population of 10,512 in the borough of Newport, the great bulk taking place between Sept. 19th and the end of November. There were, in addition, 36 attacks in the barracks and prison, and 44 in other adjacent places in the rural district; these attacks also occurred essentially at the same period. And, further, there were 43 attacks which were regarded as doubtful. In seeking the cause of this very exceptional epidemic Dr. Thomson spent much time, and he discusses every possible source of the disease with much care. We can, however, only summarise his results In the matter of sewerage and drainage, the borough, barracks, prison, and other localities invaded had nothing in common, having separate systems; some places had no sewers, and even in the borough there was no special incidence of fever on any one line of sewers, although many of the culverts were defective in the extreme. General sanitary circumstances had in like manner to be set aside; there was nothing in common with them to account for the simultaneous prevalence of fever in Newport, Carisbrooke, Gunville, the prison, and the barracks. It also became clear that milk was not the agent whereby enteric fever had been suddenly disseminated over the several invaded places; but it was otherwise when the water-supply came under consideration. Of some 2660 houses in Newport only about 50 derive their water from local wells; the remainder are supplied from a public service which is in the hands of the corporation and which is derived from two wells and certain adjacent springs at the eastern end of Carisbrooke village. The wells supply the high-level service, and the springs the low-level service. One well, the old well, is sunk 23 ft. into the chalk, and then has a bore hole of 20 ft. more; and the well has no puddling of clay or other protection. The new well is 27 ft. deep and has a bore hole of 80 ft. more in depth. For 4 ft. from the surface the well is bricked and concreted, and the remainder is lined by iron cylinders. This public service goes to 121 out of 159 houses in Carisbrooke, to 67 out of 96 houses in Gunville, as also to Parkhurst Prison and the barracks. Of the 436 cases of enteric fever in Newport 432 were known consumers of the corporation water service; 4 are not known to have consumed it. Of 28 persons attacked in Carisbrooke 25 had drunk unboiled Newport water, 2 are not known to have drunk it, and 1 was removed ill from Newport to Carisbrooke. In Gunville all the 7 persons, out of a population of 295, who were attacked were consumers of the public water-supply; and the same applies to the prison and the barracks. There is a very considerable aggregation of houses in the vicinity of the waterworks; many of the Carisbrooke houses drain into cesspools which, like the wells, are sunk in the chalk. Two cesspools, 15 ft. and 20 ft. deep, were simply disused wells; and the general trend of water in the chalk towards the bottom of the valley would lead to cesspool soakage gaining access to the chalk water. A mill pond close by has also soakage from privies &c. fouling it, and the level of the mill-pond water is such as to facilitate soakage of its contents into the low-level reservoir of the waterworks. As the result of throwing lithium into this mill-pond it was recovered from the reservoir and from the old well.

Digitized by Google

None was traced in the new well. Water taken from the low-level reservoir was found to contain the bacillus coli communis and the bacillus fluorescens putidus; and the latter bacillus was also found in the old well water. Similarly the bacillus coli was found in water taken from a tap in Parkhurst Prison; and when the corporation had samples of their water examined on their own account both the bacillus coli communis and the bacillus of enteric fever were reported to have been found in it. The report, in short, supplies a body of evidence which affords the strongest possible presumption that the Newport public water served to distribute the poison of enteric fever; and circumstanced as the wells are in a neighbourhood where there had been not infrequently fever, and which is constantly the resort of strangers and visitors, there is no lack of material for surmising how the infection may have got access to the supply. Both at the prison and the barracks orders were given on Oct. 26th to boil all milk and water, and the Newport supply was cut off from the barracks on Oct. 29th. This report, which needs to be read in detail in order to be fully appreciated, coming as it does so soon after a somewhat similar one concerning the still graver epidemic at Worthing, raises very important considerations as to chalk well waters, and is in other ways a document of much interest from the etiological point of view. By means of fissures and otherwise matters are liable to reach chalk wells in the face of greater obstacles, such as those involved in distance and otherwise, than was formerly deemed to be probable. The danger to public water-supplies which results has now been proved to demonstration, and it behoves those who are responsible for advising as to the localisation and construction of chalk wells to hold the risks which have been shown to exist in constant view, and to have regard not only to the population and houses within a zone of any such well at the time of its construction, but also as to the prospects which are in view in the future. Two such stories as those which have formed the basis of the official reports on Worthing and Newport deserve the most serious consideration of sanitary authorities, medical officers of health, and water engineers.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6542 births and 4454 deaths were registered during the week ending Nov. 2nd. The annual rate of mortality in these towns, which had been 19·1 and 19·7 per 1000 in the two preceding weeks, further rose last week to 21·9. In London the rate was 21·2 per 1000, while it averaged 22·4 in the thirty-two provincial towns. The lowest rates in these towns were 12·3 in Croydon, 14·2 in Huddersfield, 15·0 in Halifax, 17·3 in Portsmouth, and 17·6 in Brighton; the highest rates were 26·2 in Burnley, 27·5 in Manchester, 30·8 in Salford, 33·1 in Blackburn, and 35·5 in Liverpool. The 4454 deaths included 590 which were referred to the principal zymotic diseases, against 670 and 583 in the two preceding weeks; of these, 150 resulted from measles, 136 from diarrhœa, 108 from diphtheria, 83 from "fever" (principally enteric), 56 from whooping-cough, 53 from scarlet fever, and 4 from small-pox. No fatal case of any of these diseases occurred last week in Norwich; in the other towns they caused the lowest death-rates in Croydon, Brighton, Halifax, Plymouth, and Nottingham, and the highest rates in Sunderland, Wolverhampton, Burnley, Salford, and Blackburn. The greatest mortality from measles occurred in Manchester, Swansea, Wolverhampton, Salford, and Blackburn; from scarlet fever in Birkenhead and Salford; from whooping-cough in Burnley, Liverpool, and Bradford; from "fever" in Preston, Salford, Sheffield, and Sunderland; and from diarrhœa in Bolton, Hull, and Burnley. The 108 deaths from diphtheria included 72 in London, 7 in Birmingham, 6 in West Ham, and 4 in Manchester. Three fatal cases of small-pox were registered in West Ham and 1 in London, but not one in any other of the thirty-three large towns. There were 106 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Nov. 2nd, against 158, 119, and 114 at the end of the three preceding weeks; 29 new cases were admitted during the week, against 9, 7, and 14 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2841, against 2827, 2838, and 2833 on the three preceding Saturdays; 215 new cases were admitted during the week, against 332, 241, and 269 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 158 to 235 in the three preceding weeks, further rose to 366 last week, but were 28 below the corrected average. The causes of 66, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Cardiff, Bradford, Leeds, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Huddersfield, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·7 and 18·9 per 1000 in the two preceding weeks, further rose to 20·5 during the week ending Nov. 2nd, but was 1·4 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·1 in Leith and 17·5 in Dundee to 22·3 in Perth and 22·5 in Paisley. The 591 deaths in these towns included 25 which were referred to diarrhœa, 19 to whooping-cough, 11 to scarlet fever, 6 to "fever," 5 to diphtheria, 3 to measles, and not one to small-pox. In all, 69 deaths resulted from these principal zymotic diseases, against 91 and 65 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·4 per 1000, which was 0·4 below the mean rate last week from the same diseases in the thirty-three large English towns. The 25 fatal cases of diarrhœa exceeded by 4 the number in the preceding week, and included 10 in Glasgow and 5 in Dundee. The deaths referred to whooping-cough, which had been 13 and 11 in the two preceding weeks, rose again to 19 last week, of which 11 occurred in Glasgow, 4 in Aberdeen, and 3 in Edinburgh. The fatal cases of scarlet fever, which had increased from 4 to 10 in the four preceding weeks, further rose to 11 last week, and included 5 in Glasgow and 2 in Edinburgh. The deaths referred to different forms of fever, which had been 7 and 12 in the two preceding weeks, declined again to 6 last week, of which 4 occurred in Glasgow. The 5 fatal cases of diphtheria showed a decline of 4 from the number in the preceding week, and included 3 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 92 and 130 in the two preceding weeks, further rose to 136 last week, but were slightly below the number recorded in the corresponding week of last year. The causes of 48, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks 26·8 to 20·7 per 1000, rose again to 31·5 during the week ending Nov. 2nd. During the past five weeks of the current quarter the death-rate in the city has averaged 24·9 per 1000, the rate during the same period being 17·9 in both London and Edinburgh. The 211 deaths registered in Dublin during the week under notice showed an increase of 72 upon the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against 20 and 15 in the two preceding weeks; of these, 5 resulted from scarlet fever, 4 from diarrhœa, 2 from "fever," 1 from small-pox, 1 from diphtheria, and 1 from whooping-cough. These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 2·8 in London and 1·5 in Edinburgh. The deaths from measles, which had been 3 and 1 in the two preceding weeks, rose to 5 last week. The fatal cases of diarrhœa, which had declined from 17·6 in the three preceding weeks, further fell to 4 last week. The deaths referred to different forms of "fever," which had been 4 and 5 in the two preceding weeks, declined again to 2 last week. The 211 deaths in Dublin last week included 50 of infants under one year of age, and 44 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded those recorded in recent weeks. Eight inquest cases and 5 deaths from violence were registered; and 66, or nearly a third, of the deaths occurred in public institutions. The causes of 21, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

INDIA AND THE INDIAN MEDICAL SERVICES.

THE services of Surgeon-Captain J. G. Hojel (Bombay) are placed at the disposal of the Government of Bombay. The services of Brigade-Surgeon-Lieutenant-Colonel G. W. R. Hay (Bombay) are placed temporarily at the disposal of the Government of Bombay. Surgeon-Lieutenant-Colonel G. Hutcheson, M.D., is appointed to officiate as Inspector-General of Civil Hospitals, North-West Provinces and Oudh, until further orders. Surgeon-Lieutenant-Colonel J. W. Clarkson and Surgeon-Major C. G. W. Lowdell have respectively delivered over and received charge of the office of Deputy Sanitary Commissioner, Western Registration District.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon George Kell has been placed on the Retired List from Oct. 25th, 1895, at his own request, with permission to assume the honorary rank of Deputy-Inspector-General of Hospitals and Fleets. Staff-Surgeon Arthur Willoughby Russell has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet.

The following appointment is notified:—Fleet-Surgeon Archibald M'Kinlay to the *Howe*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Clark, 1st Banff Volunteer Artillery (Southern Division, Royal Artillery), to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 1st Gloucestershire: Surgeon-Captain J. S. Carleton to be Surgeon-Major. *Rifle:* 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Captain W. M. Vores, M.B., to be Surgeon-Major.

THE JAPANESE ARMY MEDICAL ORGANISATION.

Contrary to the general run of Blue-books, Surgeon-Colonel W. Taylor's Report on the Medico-military Arrangements of the Japanese Army in the Field in 1894 and 1895, is an interesting document containing much readable matter dealing with the organisation of the medical field service in Japan. The principal general hospitals at the base of operations, the field hospitals, and the dressing and regimental stations were conducted in a manner most satisfactory. One point worthy of note is the foresight with which the Japanese authorities anticipated probable requirements. They never waited till a difficulty actually arose, but had ample provision made for almost any contingency that might arise, and consequently the work was done with smoothness, regularity, and ease. Considering the efficiency of these departments of the Japanese war service, however, their ignorance of sanitation was not a little surprising. At the beginning of the late war it is true they had "Orders for the Field Sanitary Service," but these orders did not refer to questions of sanitation at all. Such subjects as conservancy, latrines, urinals, prevention of the fouling of wells or other sources of water-supply were not dealt with and in practice the same want of thought for all sanitary precautions, even the most ordinary, was evident. Early in March, however, they awoke to the importance of sanitary measures, and an elaborate system of drainage and sewerage was carried out in the most expeditious and admirable manner. With regard to water-supply and its means of purification each battalion carried with it a box containing appliances and materials for the chemical analysis of water, it being the duty of one of the officers to go on ahead to any proposed halting-place for the purpose of examining and reporting upon the water. Two simple filters, similar in construction to that popularly known in England as the Poor Man's filter, except that a bucket is substituted for the flower pot, are carried by each battalion, and a small pocket filter is supposed to be carried by each officer. It is satisfactory to note that no cases of septicæmia were reported in the hospitals.

THE LATE INSPECTOR-GENERAL SIR WM. MACKENZIE, K.C.B., M.D.

We briefly recorded last week the death of this officer, who had a very long and distinguished military career in India. Inspector-General Sir Wm. Mackenzie, K.C.B., C.S.I., M.D., was also honorary physician to the Queen. He was born at Dingwall, Ross-shire, in 1811, and died on the 29th ult. at his residence in Gloucester-terrace, Hyde Park, at the ripe age of eighty-four. He graduated M.A. of King's College, Aberdeen, in 1830, M.R.C.S. London in 1832, entered the Madras Medical Service in 1835, and became M.D. of Aberdeen University in 1856. Few men possessed a longer or more distinguished war service than did the late Sir Wm. Mackenzie, as may be seen from the following record. He served with the Ellickpur Force of the Nizam of Hyderabad's army in 1841, and again in 1851 against insurgent Rohillas; as Staff Surgeon to the 1st Brigade Central India Field Force, under Major-General Sir Hugh Rose, during the whole of the campaign of 1857–58, and was present at the engagement before Dhar, the cavalry action at Chicklia, siege of Dhar; operations at Mundersore on Nov. 21st, 22nd, 23rd, and 24th, 1857; siege of the Fort of Chanderee from March 6th till the final assault on March 17th, 1858; general action at the Betwah on April 1st, 1858; the assault on the Fort of Jhansi, April 3rd, and subsequent operations; the taking of Koonch, May 7th, 1858; the engagement at Goolowlee, May 23rd, 1858; capture of Calpee, May 22nd, 1858; engagement at Morar, June 16th, 1858; and subsequent attack on Gwalior, with pursuing column under General Napier, and engagement at Jowrah Allipore. He also served as staff surgeon to the Bearer Field Force from November, 1858, to March, 1859, and was present at the engagement of Chichumbah on Jan. 15th, 1859. For these services he was in 1859 awarded the C.B., and in 1867 the C.S.I.; he was appointed honorary physician to the Queen in 1857, and subsequently K.C.B. He was Inspector-General of the Madras Medical Department and retired in 1871.

THE MALARIA PARASITE.

The Anglo-Indian papers of the latest date contain some further communications and information regarding Surgeon-Lieutenant-Colonel Lawrie's researches as to the non-existence of Laveran's polymorphic parasitic bodies in the blood of malarious patients, to which we have already alluded more than once. It appears that Surgeon-Captain Patrick Hehir, M.D., who is regarded as an excellent microscopist and has greatly devoted himself to the study of blood parasites, had been invited to demonstrate the malaria parasite, but it is alleged that he failed to convince those who examined his specimens at Hyderabad that they were other than illusory appearances. Surgeon-Lieutenant-Colonel Lawrie is quite prepared to maintain that he has demonstrated the fact that Laveran's parasitic forms are in reality but altered white blood-cells. A full and detailed report of the Hyderabad researches is, meanwhile, as we have already said, awaited with much interest.

THE DINNER TO THE DUKE OF CAMBRIDGE.

The dinner given to Field-Marshal H.R.H. the Duke of Cambridge by the War Office officials at the Cafe Monico on Tuesday, Nov. 5th last, was attended by some two hundred guests, including not only men who have made themselves conspicuous by their valour in the military service of the country, but also some distinguished civilians. The Marquis of Lansdowne, who presided, proposed the toast of the evening in felicitous terms, remarking on the distinguished services of His Royal Highness to the country. In his reply the Duke, in a dignified and highly sympathetic manner, referred to his endeavours not to retard any improvement for the benefit of the Army and to his ready acquiescence in any change likely to benefit a colleague.

DEATHS IN THE SERVICES.

Surgeon-General J. A. C. Hutchinson, M.D., I.M.S. (retired), at Bedford on the 26th ult., aged sixty-seven years. He retired in 1884.—Deputy-Surgeon-General Robert Sander Bateson, I.M.S. (retired), on the 25th ult., at Lancaster, aged sixty-four years. The late officer served during the Indian Mutiny and was at the actions near Agra and in the engagement with Tantia Topee at Dowsa.

Surgeon-Major-General T. Walsh, principal medical officer of the Bengal Command, is about to proceed home on medical certificate, and Surgeon-Colonel T. Maunsell, it is reported, will officiate in his stead.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, the 4th inst., Sir James Crichton Browne presiding. The managers reported that the late Mr. John Bell Sedgwick, M.R.I., had bequeathed £300 to the Royal Institution in aid of the Fund for the Promotion of Experimental Research at Low Temperatures. The special thanks of the members were returned to Sir Frederick Abel, Bart., for his donation of £50 to the same fund.

"Audi alteram partem."

THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—I am sorry once more to be obliged to make an appeal to the profession on behalf of the British Medical Benevolent Fund, but for the last few months we have at every meeting of the committee overdrawn our account at the bank and have even then been unable to afford assistance in many cases where it was felt that help ought to be rendered. In September £44 was all the money available, and six grants were made, amounting to £50. At the meeting on Tuesday, Oct. 29th, there were twenty cases to be considered, besides those postponed from September, and only £34 was in hand to meet the claims, and, till the end of the year, there is no prospect of improvement in our financial condition unless through the response of the profession to our appeal.

During the year 174 cases have come before the committee and 119 grants have been made, amounting to £1083. This gives an average of about £9; but, as a matter of fact, our grants, to be of the greatest use, require to be £12 or £18, so as to enable a monthly instalment of £1 or 30*s.* to be paid throughout the year, and lately we have been obliged to reduce the allowance to the inadequate sum of £5 or £6, sometimes with the promise that a second application may be sent in at the end of six months if funds permit.

Applications and the severity of the cases which come before us increase year by year, and the subscriptions and donations, on which we depend, do not keep pace with them. The working expenses of the fund are extremely small; there is no rent for offices, no expenditure on advertisements, and no payment of officers except for clerical assistance, which is absolutely necessary, as the mere writing connected with the investigation of cases and the collection of funds and keeping accounts has become more than could reasonably be expected of men who have other work to do. The cases selected for relief at the last meeting are illustrations of the everyday work of the fund.

1. A widow aged thirty-five, whose husband had become incurably insane after two years' illness. She has three young children, and is penniless. Granted £12, ought to have been £18.

2. A medical man aged seventy-eight, quite unfit to work. Two daughters at home, one an invalid, the other recovering from scarlet fever. Granted £12.

3. A widow with young children and unable to earn anything on account of influenza. Granted £6.

4. A lady sixty-six years of age and quite deaf. Granted £6 for six months.

5. A lady who has maintained herself as a midwife, but is now too infirm to undertake cases. Granted £6.

6. A governess aged thirty-three, who has been obliged to relinquish work on account of illness. Granted £5.

These show the urgency of the distress, and I may mention that a member of the committee has already sent me a donation of twenty guineas.

I am, Sirs, yours faithfully,

W. H. BROADBENT,
Treasurer, British Medical Benevolent Fund.

Brook-street, Nov. 5th, 1895.

"THE BATTLE OF THE CLUBS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 21st your Special Commissioner asks the question, What is to be done if men are imported from other towns? with reference to the attempt of the Portsmouth men to combat the action of the members of the clubs in forcing them to attend their wives and children on their own terms. I venture to assert that the answer to that question is a simple one—viz., join the Incorporated Medical Practitioners' Association. Our aim and intention are to unite all the medical men, especially those in general practice, for mutual defence and support; call it a trades-union if you like—union is strength. We have been successful in establishing a branch for Devon and Cornwall, and we intend to take measures to establish branches all over the country, having a branch for divisions or counties, with sub-branches for towns. The members of the Devon and Cornwall branch have signed a declaration similar to that referred to by your Special Commissioner as being signed by the men at Eastbourne.

We have been successful to a very great extent in preventing the London and Manchester Industrial Society, which works a medical aid branch in connexion with, and to help, their insurance work, from extending and establishing itself here. The Incorporated Medical Practitioners' Association, having its headquarters in London and having branches all over the kingdom, will be able, in great measure, to defeat the aims of such societies as the National Medical Aid Society. Associations such as the Portsmouth and the Eastbourne ones will find their hands strengthened by affiliating themselves to us. It is true there are many men who are quite independent of the sort of work which these societies—i.e., National Medical Aid Associations, &c.—take up, but I think that the saying "that man does not live for himself alone" should be remembered by such persons. Looking at it from the point of view of such men, I think they should remember that this sort of thing has a tendency to spread, and that the public, like tigers having once tasted blood, long for more. Perhaps they will say, with Louis XV., "Après moi le déluge." If so, all I can say is that such men are selfish in the extreme and deserve no consideration whatever. I think, therefore, if all men in general practice would join our association and help to form branches in their own neighbourhood much benefit will result to the medical profession, and indirectly, by getting the work better done, to the public as well.—I am, Sirs, yours sincerely,

GEO. JACKSON, F.R.C.S. Eng. (Exam.),
President of the Incorporated Medical Practitioners' Association.

Portland-villas, Plymouth.

To the Editors of THE LANCET.

SIRS,—The enclosed cards are, to my mind, proof of the low state of the medical profession in ————. The medical man whose name is on one of the cards is styled "Dr.," and on his door-plate the same title is used; but reference to the Medical Register for 1895 shows him to have no proper right to the style. He is the holder of several local appointments. The payment made by the Liverpool Victoria Legal Friendly Society (see card enclosed) is only ½*d.* per week per head, and I suppose the agent deducts a commission. Is it not a direct violation of the oath we take to uphold the dignity of the profession to accept such pay? There are other medical men in the town, and these men will not have anything to do with the Liverpool Victoria Legal Friendly Society or the National Medical Aid Company.

I am, Sirs, yours faithfully,

C. F. HARDING.

*** Dr. Harding encloses specimens of the cards of membership of the Liverpool Victoria Legal Friendly Society and the National Medical Aid Company, Limited. The general style of these is probably known to the readers of our articles, and the way in which the two companies work together was explained in our Special Commissioner's letter from Eastbourne.[1] To secure life assurances the former of these companies became intimately associated with the latter, finding it easier to persuade people to insure against sickness than to insure their lives. The canvassers, therefore, point out the advantage of belonging to the National Medical Aid Company, Limited—only 6*d.* entrance fee for individual or family, 1*d.* a week for adults, ½*d.* a week for persons under fourteen, for medical advice, attendance, and medicine!—afterwards explaining that such medical insurance cannot be effected unless the individual insures his life, and the insurance is granted by the Liverpool Victoria Legal Friendly Society. We do not know if the agent in this case deducts any commission, or whether the medical man gets the whole of the

[1] The Battle of the Clubs, THE LANCET, Oct. 5th, 1895.

Digitized by Google

halfpenny, but we agree with our correspondent that it is deplorable that such fees should be taken.—ED. L.

To the Editors of THE LANCET.

SIRS,—Your article on the subject of the "Battle of the Clubs" in your issue of Oct. 12th contains a reference to this Company which is inaccurate in fact and calculated to mislead. You refer to this Company as one of two assurance companies which combine "medical aid association" with their own proper business. The transactions of this Company, however, are confined exclusively to life assurance, and medical aid forms no part of the Company's operations. In certain cases, I believe, the agents of the Company do introduce persons to medical men who are willing to attend patients at a fee settled by the medical men themselves, and which is collected by persons appointed and remunerated solely by them, and with which our agents have nothing to do. The Company has for years past had only one medical referee at Eastbourne, and he alone reports and receives remuneration from us. I find that the Company's agents have introduced certain persons for medical attendance to one other medical gentleman, who has had a club, but he has no connexion with the Company, and the introductions in question were quite unknown to the Company. I am informed that he has joined the Association lately formed at Eastbourne, but there has been no abandonment of connexion with the Company, for it never existed, and the statement that three medical officers of the Prudential have abandoned their connexion with this Company has no foundation in fact. The real facts of the matter were stated in your issue of Oct. 5th, and I can only suppose that the reference to the Company contained in your issue of the following week was an inadvertence.

I am, Sirs, yours faithfully,
T. C. DEWEY, Manager.

Prudential Assurance Company, Limited, Holborn-Bars, London, Oct. 31st, 1895.

*** We have compared our article of Oct. 12th with that of our Special Commissioner which appeared on Oct. 5th, and regret that we should have alluded to the Prudential Assurance Company, Limited, as offering medical aid to their members. As will be seen from Mr. Dewey's letter there were circumstances that might well lead us to the conclusion we arrived at. We have before now in our columns testified to our sense of the value of the work that is done by the Prudential Assurance Company, Limited, and are glad to publish their disclaimer of all association with the methods employed by sick-aid institutions.—ED. L.

THE ADMINISTRATION OF CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—Your criticism in THE LANCET of Oct. 26th of the use of lint as productive of dangerous concentration of vapour during the administration of chloroform induces me to put forward some arguments for and against the different inhalers that are in use. In administering chloroform two points are of vital importance. First, the administrator should be fully cognisant at every moment of the amount of chloroform vapour which the patient is *at that moment* inhaling. Secondly, an equable quantity of vapour should be maintained, and therefore the chloroform should be added drop by drop. The use of one corner of a new and therefore fairly stiff white towel pinched up into the form of a cone fulfils both these conditions. Chloroform can be dropped on the outside of this drop by drop, and on this texture it produces a wet, dark stain the intensity of which is a visible index to the chloroformist of the quantity of vapour at each instant being presented to the patient. The size of the cone can be adjusted to the requirements of each case, and as soon as one corner begins to show the wet stain less distinctly, becoming limp from the moisture in the patient's breath, one of the other corners can be substituted for it. The quantity being thus appreciated by the eye and its effect on the patient noted, the chloroformist attains, after practice with this method, to some control over, and precision in, dosage, and can tell approximately the number of drops that should be put on the towel at the various stages of anæsthesia. This, together with a full knowledge of the signs of these stages, on the one hand, enables him to avoid concentration of vapour, especially at times of excessive absorption or of defective elimination, and, on the other hand, emboldens him to give a sufficient quantity to prevent the occurrence of incomplete anæsthesia, with its risks to the patient, to say nothing of the annoyance to the operator and anæsthetist.

The objections to the other inhalers may now be briefly considered. The least objectionable appears to be the Scotch method, in which chloroform is poured on the upper margin of a folded towel which is held round the patient's face. The free admission of air that is allowed certainly lessens the risk from concentration of vapour, but as there is more than a single layer of cloth to absorb the chloroform the intensity of the wet stain is no indication of the quantity of chloroform being inhaled. There is also unnecessary waste in the method, a large quantity of vapour being lost and causing annoyance to the administrator. Similarly, Junker's inhaler, while well diluting the vapour, affords no indication of the dose actually being given. Finally, the materials in greatest use as inhalers are flannel and lint, and neither of these shows a distinct wet stain with chloroform. Of 35 fatalities under chloroform from 1892 to 1894, where the form of inhaler used is mentioned, it was in 43 per cent. lint and in 25·7 per cent. flannel—i.e., Skinner's inhaler—against 14·3 per cent. in which a towel was employed. Further, the metal rim of Skinner's inhaler interferes with the evaporation of the vapour and allows drops to fall on the patient's face; and with a double fold of lint an equable quantity of vapour cannot be maintained, sudden concentration being apt to occur whenever the lint is turned after a fresh supply has been added. Of course, the choice of the inhaler is only one detail to ensure the safe administration of chloroform; but I consider that the method I advocate, being more accurate than any other, deserves a wider application than it at present has, and should, until some better method is discovered, displace lint and the other forms of inhalers now in use.

I am, Sirs, yours faithfully,
HOWARD GLADSTONE, M.D., C.M.

Royal Chest Hospital, City-road, E.C., Oct. 29th, 1895.

To the Editors of THE LANCET.

SIRS,—Under the heading of "Death under Chloroform" we constantly read "the chloroform was administered in the usual way." I would ask what is the usual way: is it with or without an inhaler? Both ways cannot be "best," so which is? Is the percentage of deaths more or less with the inhaler, as compared with the percentage of deaths (if any) where chloroform is administered on the Edinburgh plan? The only inhalers I ever saw in Edinburgh were those which Sir Jas. Y. Simpson (ah! how many years ago) used to show on his lecture table as interesting relics of a bygone age. In England and America I have seen chloroform administered by inhalers, and without even after stertor had set in, which both Syme and Simpson taught all their pupils was an alarming "danger signal." We did not think a great deal about what quantity of chloroform we gave in those days, but the chloroform *towel* was pretty quickly removed if a suspicion of stertor occurred. I wonder a coroner's first question in all such cases is not, "Did you use an inhaler?"

I am, Sirs, yours faithfully,
R. WHITTINGTON LOWE, M.D. Edin.

Park-place, Nov. 4th, 1895.

*** The ambiguity of the expression is matter of regret. The "usual way" commonly means that chloroform is exhibited from a towel or piece of lint. The number of deaths in which the "open method" is employed largely exceeds that where an inhaler is used, but as the former plan is so much more frequently adopted it is impossible to trust to statistics in attempting to arrive at a decision upon the relative safety of the methods. There have been several deaths under the Edinburgh method, as indeed in the case of every known way of administering chloroform. The use of a towel-end is advocated in some places, but cannot be regarded as being exact since the amount of vapour which reaches the patient must depend upon varying quantities—e.g., the temperature of the room, the vigour of the respiration of the patient, the texture of the towel, &c. With many inhalers an

Digitized by Google

exact quantity of chloroform is evaporated in a given time and mixes in a known proportion with the inspired air; and, further, the proportion of chloroform can be lessened at will or can be maintained constant. This cannot be done with the rough-and-ready "open method." The teaching in London of Snow, Clover, and their followers has always been to regard "stertor" as an evidence of obstructed breathing, and to insist upon the extreme danger of that symptom. In no well taught London hospital would a student be permitted to continue the inhalation of chloroform to a stertorous patient.—ED. L.

"DUBLIN INFECTIOUS HOSPITALS SCHEME."

To the Editors of THE LANCET.

SIRS,—In reference to the above subject, permit me to make the following statements, which I submit to the judgment of your readers. 1. The draft scheme for providing isolation hospitals outside the city of Dublin was drafted by me and submitted to Mr. Stafford, the medical inspector of the Local Government Board of Ireland. Mr. Stafford amended the scheme, and it was then submitted to and approved of by the Public Health Committee. 2. The scheme was submitted to a conference of representatives of the local sanitary authorities, and it was distinctly stated to them that the scheme could be modified in any way provided that provisions were made in it for establishing one or more hospitals for small-pox and a home for convalescents from infectious diseases outside the city. 3. In the draft scheme no reference is made to the existing Dublin hospitals, and a motion made at the conference to consider the question of the public money grants made to them was spoken against by me and was rejected. 4. In the recent small-pox epidemic there was not sufficient accommodation for the patients in the fever hospitals, and hundreds—chiefly convalescing cases—were obliged to go into the workhouse hospital. 5. The council of the Dublin Sanitary Association played a sorry part when they tried to stifle a scheme which was chiefly designed to provide a proper hospital for small-pox and a home for convalescents from infectious diseases. It is a new departure for a sanitary association to show solicitude for the ratepayers and apprehension that the establishment of isolation hospitals might interfere with medical education. 6. It is a pleasure to me to be able to state that at the beginning of our small-pox epidemic the authorities of the general hospitals at once agreed not to admit small-pox cases. I trust the time is not far off when they will extend the exclusion to a few other infectious diseases—scarlet fever and typhus fever, for example. There are in Dublin eight general hospitals (some of them with maternity departments) in which fever cases are received.—I am, Sirs, your obedient servant,

CHARLES A. CAMERON,
Superintendent Medical Officer of Health.

Public Health Office, Dublin, Nov. 2nd, 1895.

THE EFFECT OF CHRONIC NASAL OBSTRUCTION ON THE GROWING SKULLS OF YOUNG PERSONS.

To the Editors of THE LANCET.

SIRS,—Will you permit me to call attention to a point I have long insisted on—namely, the irreparable damage done to the growing upper maxillary bones, and consequently to the facial appearance, of young persons the subjects of chronic nasal obstruction? I have observed in a multitude of instances the constant association of narrow, flattened faces, pinched upper lips, highly arched palates, and crowded, irregular teeth with chronic nasal obstruction in one form or another, notably with deflected septa and turbinal hypertrophies and engorgements. Continental and American authors have frequently noticed this association, but apparently have not hit upon the relation of one to the other. For instance, Trendelenburg has pointed out the frequent association of highly arched palates with deflections of the nasal septum. Jarvis has reported a series of four cases in the same family, and thinks they are hereditary. Bosworth and many others have noticed the same association and have offered various explanations, none of which appear to me sufficient.

I venture to think Ziem has set the matter at rest by his experiments. Ziem has proved that every obstruction of the nose exerts widely spread consequences on the development of the skull in young animals, one of whose nostrils he completely closed up for a long time. There was seen a deviation of the intermaxillary bone and sagittal suture towards the shut-up side; also lesser length of the nasal bone, of the frontal bone, and of the horizontal plate of the palate bone; and less steep elevations of the alveolar processes; smaller distance between the anterior surface of the bony auditory capsule and the alveolar process, also between the zygomatic arch and supra-orbital border; and smaller size and asymmetrical position of the vascular and nerve canals on the closed side of the nose. The distance of the two orbits from the middle line was unequal, which, as has been observed in man, leads to asthenopia, astigmatism, and strabismus.

I am, Sirs, your obedient servant,

Harley-street, W., November, 1895. MAYO COLLIER.

"THE PHYSIOLOGY OF DEATH BY ELECTRIC SHOCK."

To the Editors of THE LANCET.

SIRS,—One result of the publication of my letter in your issue of Oct. 26th has been that a former pupil of mine (Mr. Charles H. Piesse) has done me the favour to send me a reference to an interesting paper in THE LANCET of Oct. 4th, 1890, by Mr. Percy Pope. For the benefit of those of your readers who may not be able to refer back to that number of THE LANCET I beg permission to state briefly the main points of the lucid narrative.

A number of soldiers at Aldershot were stationed under some small trees watching a cricket match when a sudden flash of lightning, like the bursting of a shell, was followed by cries for help from the men under one particular tree. Five men were found to have been more or less injured. No. 1, who had been sitting on the ground with his back against a tree from which a portion of bark had been stripped close to his head, was dead; the breathing and pulse had ceased and artificial respiration failed to revive him. No. 2 was quite unconscious; the respiration had ceased, but the pulse was still perceptible. "In this case artificial respiration was rewarded after some minutes by a gradual return to consciousness." Brandy was then given; he was removed to hospital and soon recovered. Nos. 3, 4, and 5 recovered consciousness without artificial respiration some few minutes after being struck. The state of the pulse and breathing during the brief unconscious period is not mentioned. All the four men were able to return to duty within a few days. It is remarkable that the man who was killed had no marks of injury on the head or face, but No. 2 had his hair singed, and there were marks of burning (like ecchymosis) on the left side of the face, neck, and upper part of the chest.

These cases afford interesting illustrations of three degrees of injury from lightning shock. No. 1 was fatally injured, with simultaneous arrest of the heart's action and breathing; No. 2 was unconscious, with suspended breathing, but was restored by artificial respiration; and Nos. 3, 4, and 5, temporarily unconscious, probably with suspended breathing, recovered from the shock without special assistance. The practical lesson is that *one man's life was saved by artificial respiration.* Some interesting particulars were given of the condition of the patients after the return of consciousness, but with these I need not occupy your space.

I am, Sirs, yours faithfully,

Savile-row, Nov. 4th, 1895. GEORGE JOHNSON.

"A VERY EFFECTUAL METHOD OF TREATING MALIGNANT DISEASE OF THE BREAST."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 12th, 1895, under the above heading, appears an article by Mr. Arbuthnot Lane. I have on two occasions performed an operation exactly similar to the one he describes for recurrent scirrhus of the breast, with the exception that the third part of the subclavian

Digitized by Google

artery in my cases was tied without preliminary resection of the clavicle. Both of these patients recovered from the operation. The first case was operated upon on May 30th, 1893, and full notes of the condition and operation are published in the Edinburgh Hospital Reports for 1894, page 480. This patient died in August, 1894, and I am indebted to Dr. Herbert E. Hick of Bradford, under whose care she was, for a note of her condition when she died. He says: "The operation was a complete success, as up to the time of her death there was no sign of recurrence of the disease in the neighbourhood of the scar." She died from a rapidly growing malignant tumour of the stomach. The second case has been operated upon too recently to make any further note of it useful, but so far as I can judge the whole of the diseased structures were excised, and this would have been impossible by any other method.

I am, Sirs, yours faithfully,

RUTHERFORD MORISON.

Saville-row, Newcastle-on-Tyne, Nov. 5th, 1895.

"THERAPEUTIC VALUE OF INTESTINAL ASEPSIS."

To the Editors of THE LANCET.

SIRS,—I read with great interest Dr. Williams's paper on the treatment of typhoid fever by the chlorine mixture. The only drawback I have found is the difficulty patients have in taking it; in several of my cases it has produced retching for some time afterwards. The mixture has invariably brought down the temperature, and with the above exception has generally improved symptoms. With regard to sulphurous acid, patients take it well and with the best results. The dose I generally prescribe is half a drachm to one drachm freely diluted with water, every three or four hours.

I am, Sirs, yours truly,

Khedive-road, Upton, Nov. 2nd, 1895. E. H. BLAKE.

To the Editors of THE LANCET.

SIRS,—Dr. Burney Yeo has drawn my attention to a mistake I made in attributing to him the first use of the chlorine treatment in "typhoid" &c., and has referred me to his book, in which I should find references to "Watson, Murchison, and others." I see that Dr. Williams speaks of the benefit of this treatment as "recommended" by Dr. Yeo. I take this opportunity, in common fairness to Dr. Yeo, of making this statement.

I am, Sirs, yours truly,

Harrow-road, Nov. 5th, 1895. A. L. GRIFFITH.

"THE ADMINISTRATION OF OATHS IN COURTS OF LAW."

To the Editors of THE LANCET.

SIRS,—The quotation given by Dr. Bullock is also given in Notes and Queries, Fourth Series, Vol. X., p. 119. I believe it was the practice to lay the hand upon the book "*tactis sacro-sanctis Dei evangeliis.*" The same publication mentions other curious facts in connexion with oath-taking, one being that in certain parts of Ireland it was formerly considered unlucky for a pregnant woman to take an oath within a certain period of her delivery. But no mention is made of the date when "kissing the book" first began, though this question was specifically asked by a correspondent twenty-three years ago. The Scotch oath is also mentioned, but no reason is given for the different mode of adjuration in England, Wales, and Ireland on the one hand, and in Scotland and the Channel Islands on the other. Can any of your readers help us to discover this?

I am, Sirs, yours faithfully,

Liverpool, Nov. 4th, 1895. FRED. W. LOWNDES.

THE INFLUENCE OF HOT AND COLD DRINKS ON THE TEMPERATURE IN THE MOUTH.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 26th Dr. Lazarus Barlow drew attention to the influence of hot and cold drinks on the temperature in the mouth. I have often thought that one might easily be misled if the temperature were taken in the mouth too soon after food. Two instances which have recently occurred to me show this. A few weeks ago I saw a boy suffering from tonsillitis. His mother, a few minutes before my arrival, had taken his temperature in the mouth and found it to be 102° F. I took it in the mouth and found it to be 100°. Our thermometers were tested and found to agree. On inquiry I found that he had had some hot beef-tea just before his mother took his temperature. The second instance occurred yesterday, when I saw a boy who had symptoms of influenza. Immediately on going into the room I put my thermometer in his mouth, when it registered 104°. Doubting the accuracy of this, I put it under his arm and found it registered 99°. After waiting a little while I put it in his mouth again, and found it registered 100·2°. Just before my arrival he had taken a glass of very hot milk. These two cases show how easily one may be deceived if one trusts entirely to the thermometer.

I am, Sirs, yours faithfully,

Bedford, Nov. 6th, 1895. W. GIFFORD NASH.

"BERI-BERI."

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of Sept. 21st a letter with the above heading which may possibly lead to some misconception, as the disease described—which is a very common and troublesome one among tea garden coolies, and of which Dr. Sheperd has given a perfectly correct account—is certainly not beri-beri but anchylostomiasis. There are intense anæmia and hydræmia, but none of the characteristic symptoms of beri-beri — no peripheral neuritis or any affection of the great nerves supplying the heart and lungs. It has certainly for a long time been known locally as beri-beri, owing, doubtless, to some misconception on the part of the practitioners who saw the earlier cases. The appearance of the patients is characteristic, but if any doubt exists as to the diagnosis of a particular case a simple microscopic examination of the fæces will, if they are present, instantly reveal the large non-operculated segmented ova without the trouble of washing out the worms. There is a delicate shell having a single contour, non-operculated, enclosing a segmented yelk separated from the shell by a colourless fluid. A good illustration of this and other intestinal ova will be found in "Davidson's Hygiene and Diseases of Warm Climates." With regard to the administration of thymol, I have never had any bad symptoms, even in delicate children, and I have given it to babies six months old. The proper way to administer it is dry, in which case very little is absorbed and the worm gets the full benefit of the dose. The effect of thirty grains given in ten-grain doses at four hours' interval is often magical, the anasarca disappearing before other treatment can be resorted to. I have never seen the slightest mental disturbance. A certain proportion of the cases are inveterate, and it will generally be found that these are earth-eaters. The coolies themselves recognise this. The curious part of it is that they cook the earth. I have never been able to discover the worm embryo or egg in earth or water, but have little doubt it develops in the soil. I do not know whether the disease is prevalent among the indigenous local population (the coolies are all imported and live under special local conditions), but I fancy not. I quite recognise the force of Dr. Sheperd's remarks as to the importance of the early recognition of the disease in ship's crews, emigrant coolies, and others, but must emphasise my objections to having thus easily cured disease confounded even verbally with such a serious disorder as beri-beri. A confusion of terms easily leads to confusion of diagnosis. I should be much obliged if any of your readers could give me an account, clinical, nosological, &c., of the disease known as "kala azar" which is so prevalent in some parts of Assam. I shall be happy, if you wish, to send you specimens and microphotographs of the eggs.

I am, Sirs, yours truly,

CHAS. E. SEAL, M.R.C.S.

Chundiechena Tea Estate, S. Sylhet, Oct. 11th, 1895.

PRESENTATION. — Mr. Algernon Sudlow, M.R.C.S., of Castle-Combe, Chippenham, has been presented by his friends, on retirement from the profession after forty-three years' practice in that village, with an illuminated address and a cheque for £150. The presentation was made, on behalf of the subscribers, by Sir A. Neeld, the high sheriff.

Digitized by Google

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday.

THE amount collected on Oct. 27th reached the sum of £4264 9*s.* 3*d.*, which goes this year to the General Hospital.

Hospital Saturday.

The annual reunion of the patients of the convalescent homes at Tyn-y-Coed and Marle Hall took place in the town hall on the 4th inst. The object is to keep up the interest of those who have passed through the homes in the Hospital Saturday movement. Over 3000 invitations were issued, of which some 250 were returned through the dead letter office on account of change of residence. Up to the present time, the fourth annual meeting, 2075 men and 586 women have passed through the two homes. Mr. Smedley, the President, claimed for the homes that they would bear comparison with any similar institutions in the country for their surroundings and appointments, for the liberality of the fare, and for the advantages which the patients enjoyed. A presentation of a writing table was made to Dr. Woodhouse, one of the honorary surgeons, and a similar gift to Mrs. Woodhouse. The police band rendered efficient service, and a pleasant evening was spent.

Medical Mission.

The twentieth annual meeting of the Birmingham Medical Mission was held on Oct. 24th. The report stated that the past year had been one of unusual activity. The number of patients treated was the largest there had been, 5832 having received the benefits of the mission. The consultations given at the stations and at the homes of the poor were 26,698, while the staff consisted of one medical man, an apothecary, a general helper, and one nurse. It may be inferred from this that much energy must have been displayed, and that very little spare time was available. The cost per patient was about 2*s.* 6*d.* When the distress of last winter was at its height about 250 families were daily relieved, and breakfast for 180 was provided three times a week to the sick poor. Garments, boots, and shoes were also distributed. The income was £858 18*s.* 7*d.*, and after payment of expenses a balance of £134 remained in hand.

The Burial of Stillborn Children.

In a former note the discovery of unburied stillborn children in a house in the town was alluded to. The city coroner, Mr. Oliver Pemberton, in holding an inquest upon the bodies, made some valuable suggestions as to dealing with such cases. He proposed that the parents of such children shall be required to give notice within a specified time to the registrar of the district; that the registrar shall record this and give an order for burial, which shall take place within a given time; also that the registration shall be made in the books at the cemetery. In case of undue delay notice shall be given to the police authorities, and it shall be unlawful for undertakers or other persons to keep the bodies of stillborn children on their premises other than a reasonable time before burial. If these recommendations are carried out they will go far to prevent the laxity and carelessness which are common in dealing with this evil, a prevalent one unfortunately in all large towns.

Obesity and Old Age.

That this combination is capable of existing was lately proved at Cradley Heath by the death of a resident at the advanced age of eighty-four. He weighed 26 st., and for over fifty years kept a well-known public-house in the district. Some drawbacks evidently attended his career, for he was unable to move about much and had to be hoisted up into his bed at night. Nevertheless, his long life and great weight did not interfere with his conduct of business or hinder his ordinary enjoyment.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester and Salford Sanitary Association.

AT the last meeting of the committee a suggestion made by Dr. Niven in his annual report on the health of Manchester, with reference to securing a milk-supply of guaranteed purity through the agency of a company or association, was considered and referred to a standing committee. The question of poisoning by carbolic acid was also introduced with a view to an effort being made to get it scheduled as a poison, but action was deferred till certain statistics could be obtained. The subject of accidents owing to the use of inferior oils and of badly constructed lamps was next considered, and it was decided to memorialise the Home Secretary with reference to having the standard flashing point raised for illuminating oils. It is said that in the United States, notwithstanding the great use of oil lamps and stoves, comparatively few explosions take place, owing no doubt to the fact that the flashing point of the oil used is so much higher than it is in this country.

Children's Holiday Fund.

The object of this most useful charity, which held its annual meeting the other day, is to send poor children into the country for a three weeks' holiday. The report gave a somewhat discouraging view of its position. Whatever the cause—whether due to the general and long-continued depression of trade (from which, however, we are now said to be recovering) or to a growing indifference to suffering and misfortune—the fact remains that hospitals and charities of all kinds have for some time told the same story of crippled means. In the present case it is stated that the committee began their work this year with an adverse balance of £286 and a falling off in the subscriptions, so they had been unable to give a holiday to the usual number. This led to their sending "only delicate children or such as absolutely required a change." Thanks were given to the medical men who had examined the children and given the necessary certificates before they were sent to the country, and to the Manchester press for their references to the work done by the society. The honorary treasurer, in moving the adoption of the report, said the committee deeply regretted that they had to curtail their work. Last year more than 1200 children were sent for a holiday, while this year the number had fallen to 385. The Lady Mayoress, who occupied the chair, commended the society's work and hoped the coming year would bring increased funds.

Manchester Edinburgh University Club.

The members of this club had their annual dinner on the 21st ult. Though open to all professions, that of medicine is most numerously represented. The guest of the evening was the Rev. John Watson of Liverpool, better known perhaps as "Ian Maclaren," the author of "Beside the Bonnie Briar Bush." When speaking in response to the toast of his health, Mr. Watson referred to some remarks made by its proposer as to the tribute he had paid in his book to the medical profession. He had tried, he said, to express the feeling of gratitude which he believed every person in the community, but especially people who lived in country districts, and most of all country clergy, had for the country members of the medical profession. He had said nothing in his book "which could not be verified in actual lives known to himself and to other men."

The Vegetarians.

The forty-eighth annual meeting of the Vegetarian Society was held here on the 21st ult. A paper was read by Miss Eccles, in which it was contended that vegetarianism was nothing if not religious, and that man "could not possess the simple virtues justice and honesty in their fulness while he deprived those whose right was equal to his own of the blessing of life, dearest to all of them as to him." Mr. A. W. Malcomson followed with a paper on the Æsthetic in Food, in which he urged that eating and drinking could be refined and elevated by the beauty of simplicity and purity. "Vegetarians had become possessed of a perception of what was true and beautiful and what was false and hideous in the matter of food. The occupation of a butcher and slaughterman was ostracised and debarred from all poetry and romance, all beauty, all æstheticism. No one of refined and cultured tastes, certainly no æsthete, would ever choose it"! A public meeting was held in the evening, at which a lady presided who was a Grand Vice Templar, I.O.G.T.—whatever that may be. Stress was laid on the importance of fruit culture, and it was contended that it did not receive sufficient recognition or assistance from Government and that everything should be done for the encouragement of British fruit culture. One gentleman said he once visited all the fruiterers' shops in Chester and could get no British-grown apples, though there were plenty of foreign ones. I am afraid that is very much the fault of the growers, who.

Digitized by Google

keep to their old inferior kinds, and if they have a good sort it is not well grown, is badly selected, badly packed, and offered in a less attractive condition than its foreign rival. Spade culture was advocated as opposed to the plough, especially the steam plough. It seems that many social and economic difficulties would vanish if vegetarianism prevailed. A member of Parliament of that cult was wanted to put before its members from a vegetarian standpoint "the great problem of taking labour from the congested towns to happy and healthy life on the land." Professor Mayor of Cambridge, the President of the society, said that when he first remembered Cheshire farm-houses a visitor was never offered anything purchased at a shop—it was all home-made. Now all this was reversed. Mr. Axon of Manchester, a veteran in the cause, was very enthusiastic, saying it was not merely a system of dietetics, but "something that contributed to the simplification of life, to the elevation of morals, to the improvement of life generally, and to all good causes whatsoever. ..... It was the sister of all other good movements of peace societies, purity societies, and thrift societies. The adoption of the vegetarian system by the nation would solve a great many of those grave and pressing problems which were perplexing alike statesmen and moralists all over England and Europe." This enthusiasm is harmless, and perhaps to a certain extent useful, in a nation of beef-eaters, while the vegetarians are to be congratulated on the happiness they evidently feel in being "so very superior."

Nov. 5th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

St. Oswald's Home for Friendless Girls.

THE foundation-stone of this valuable institution was laid at Cullercoats last week by Mrs. J. R. Burn, in the presence of the Bishop of Newcastle, a number of local clergymen, and others. The building is to cost £5600, of which sum Mr. J. R. Burn, with his usual liberality, has contributed £2000. The Society for Providing Homes for Waifs and Strays provides £500. The house will contain accommodation for fifty children. It is a Church of England institution.

Cruelty to Children.

Hardly a week passes without the Society for the Prevention of Cruelty to Children bringing before the magistrates in this neighbourhood cases revealing shocking neglect of children by drunken parents. Mr. Barnado says that some of the worst examples of child degradation he has met with come from Newcastle-on-Tyne. A few days ago a man and his wife were charged with exposing and neglecting their three children aged four years, two years, and six months respectively. Inspector Appleton found them all lying in an old pay office six feet square, on a miserable mattress, with only a few rags to covert hem. The children were benumbed with cold. The place was full of rags, bones, and pieces of old iron. They had slept there for four or five weeks. The infant had been born in an old coal-house. The father and mother were both drunkards. The infant weighed 9 lb. The bench sent the parents to gaol and removed the elder children permanently from their custody.

Amateur Operetta by Children.

A new operetta, *The Demon Spider*, by Miss E. G. Simpson, a grand-daughter of a well-known local medical man, and Mr. M. E. Lawson, was performed in the Art Gallery, Newcastle, on Wednesday, Oct. 30th, for the benefit of the Royal Infirmary. The house was crowded. The characters were all taken by children, and Mr. J. H. Beer, in the absence of Mr. Lawson, kindly conducted.

The Tyne Port Sanitary Authority.

At a meeting to-day of the Tyne port sanitary authority it was arranged to advertise for a medical officer in the place of Dr. H. E. Armstrong. The duties were defined and the salary fixed at £150 per annum, the officer to reside at the mouth of the river. It was suggested that Dr. H. E. Armstrong should be asked to accept the appointment of consulting medical officer, and in the public interest it is to be hoped this suggestion will be accepted, for there can be no doubt that the experience of Dr. H. E. Armstrong would be most valuable.

Tynemouth Victoria Jubilee Infirmary.

A cheque for £2000 has been received by the chairman of the above-named charity from Mr. R. T. Donkin, M.P., for the purpose of completing the hospital by the building of a new wing and a porter's lodge, and providing furniture. This generous gift of the member for the borough will be thoroughly appreciated by the inhabitants of Tynemouth.

Newcastle-on-Tyne, Nov. 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Prosecutions by the Pharmaceutical Society.

REFERENCE has already been made to prosecutions at the instance of the Pharmaceutical Society of Great Britain, against various persons charged with contravening the Pharmacy Act, 1868. Two of these cases were carried from the Sheriff's Court to the Justiciary Appeal Court. One of the cases was against Mr. Hume of Edinburgh, who designated himself a "scientific instrument maker and technical chemist" and a "photographic chemist." The other was against Mr. Turnbull, and the question raised in his case was whether he had committed the offence of keeping open shop for the retailing, dispensing, or compounding of poison. Lord Trayner, in dealing with Mr. Hume's case, recognised the difficulty of the case. The Act had been passed for the safety of the public and forbids anyone keeping open shop for retailing poisons or using the title of chemist unless qualified and registered as the statute provided. He considered that the title "technical chemist" was within the statutory prohibition. The title of chemist was used in connexion with premises in which poisons were sold in small quantities, and the public, for whose safety and protection the Act was passed, were more likely than not to regard the title "chemist" without paying any attention to, or perhaps understanding, the qualification "technical." That the prefix of a qualifying adjective to the title chemist or druggist did not take the person using such title out of the statutory prohibition had been decided in England, where "botanical chemist" and "shipping druggist" had been treated as contraventions of the statute. Had these English decisions been to a contrary effect his lordship would not have dissented from them. They would then, he must admit, have been more in accordance with the inclination of his own mind. It was not desirable, however, that an imperial statute should be interpreted differently in different parts of the kingdom, and he was, therefore, prepared to follow them and decide accordingly. In doing so his lordship was doing the respondent no wrong or even putting him to any serious inconvenience, while he was only affording to the public the protection which this statute intended. With regard to the other case, he held that the shop in question was the respondent's shop, and it was certainly kept open, *inter alia*, for the sale of poisons in small quantities. The other two judges concurred in this finding. The agent for the Pharmaceutical Society did not ask for expenses, and stated that the society only wanted the point decided. The Lord Justice Clerk approved of this, as there was nothing whatever against the character of either of the respondents. They had not acted in a surreptitious manner at all. It was only technically that the court were obliged to come to the judgment they did.

Opening of the Royal Edinburgh Hospital for Sick Children.

On Thursday last week the new buildings of the Royal Edinburgh Hospital for Sick Children were opened by Her Royal Highness Princess Beatrice, who had travelled, accompanied by Prince Henry of Battenberg, from Balmoral for this purpose. Owing to the limited accommodation at the hospital comparatively few invitations were issued for the ceremony, even the staff of the Royal Infirmary not being honoured with them. After the usual preliminaries and the formal "I declare this hospital open," Her Royal Highness was conducted over the hospital. At each of the wards the Princess was asked to hand to each of the nurses a silver badge commemorative of the occasion. These badges were the gift of the physicians and surgeons to the hospital. The Princess named one of the wards the "Beatrice" ward. The old Sick Children's Hospital was situated in Lauriston-lane, but it was demolished a few years ago and the site sold to the Royal Infirmary for its extension. Since that time a building at Morningside has been used as a temporary hospital. The

Digitized by Google

new hospital is situated on the south side of the meadows, within five to ten minutes' walk of the Royal Infirmary and the Medical School. The building is in the form of the letter E, the central block containing the administrative department, kitchen, and servants and nurses' bedrooms, as well as the medical and surgical theatres. The two arms of the building run southwards and are three storeys in height. The ground and first floors contain general wards, while the upper floors are devoted to observation, isolation, and spare wards. The four principal wards contain twenty-four cots each, the total accommodation in the hospital being 118 beds. The flooring of the wards is of teak, and the walls are finished with Parian cement polished to a smooth surface. The angles of walls and ceilings are rounded, and all ornamentation is excluded so as to avoid ledges for the harbouring of dust and microbes. Attached to the main building are an out-patients' department, mortuary, and pathological rooms, and laundry buildings. The hospital has been erected at a cost of £40,000, and seems on the whole to be a satisfactory example of the special type of hospital construction.

Edinburgh Royal Infirmary.

At the meeting of the managers of the Edinburgh Royal Infirmary on Monday a long discussion took place with reference to a sum of about £70,000 which shortly is to be paid into the coffers of the institution. It was decided that part of this money should go to wipe out the whole debt on the infirmary, which amounts to about £40,000.

The Presidency of the Royal College of Surgeons of Edinburgh.

Emeritus Professor Struthers has been elected President of the Edinburgh Royal College of Surgeons. The new president is a Fellow of some fifty years' standing.

Glasgow University.

The winter session was this year opened without any formal introductory address. At the first meeting of the class of physiology Dr. McKendrick gave an account of the work of Carl Ludwig, and discussed the limitations attending the application of physical methods of research to the problems of physiology. Professor Coats addressed his class on Ludwig and Pasteur, and claimed that the personal characters of these men of science formed a complete refutation of the statement that vivisection exercised a degrading and immoral influence on those who practised it. Professor Coats has been elected Honorary President of the Students' Medico-Chirurgical Society and has delivered an address on Immunity to Infective Diseases, Natural and Acquired. Mr. Jas. Carslaw, M.B., has been appointed Assistant to the Professor of Medicine, and Mr. Hugh Galt, M.B., Assistant to the Professor of Medical Jurisprudence. Dr. Fraser Harris is to show to the Glasgow Philosophical Society a new optical instrument known as the stereo-photo-chromoscope, the aim of which is to photograph an object in such a way that the "positive" of the picture, viewed as a transparency, will present the object with its natural colours and also with stereoscopic effects. At the meeting of the General Council on the 30th ult. considerable dissatisfaction was expressed at some of the recent Ordinances of the Universities Commission, and the opinion of several speakers, including Dr. McVail, seemed to be that the sooner the Commission was dissolved the better for the Scottish universities. Dr. McVail and the Rev. Dr. King have been re-elected as the representatives of the Council on the University Court for a further term of four years.

New Convalescent Houses for Murthly Asylum.

Two new convalescent houses have recently been erected by the Perth District Board of Lunacy, the object being to separate patients, who have to a considerable extent recovered, from association with those in whom mental disorder is still pronounced. The formal opening of the new houses took place on the 2nd inst., Lord Belvaird handing over the key of the new houses to Dr. G. M. Robertson, the medical superintendent. The visitors, amongst whom were Lord Provost Dewar of Perth and Dr. Yellowlees of Glasgow, were afterwards entertained to luncheon.

Gaelic Society of Glasgow.

At the opening meeting of this society the President, Dr. Campbell Black, delivered an address on Some Traces of Eastern Mythology in certain Celtic Superstitions.

Glasgow and the British Institute of Public Health.

The Institute has accepted an invitation from the corporation to hold their annual meeting next year in Glasgow, and a committee has been appointed to make the arrangements necessary for their reception.

Glasgow Obstetrical and Gynæcological Society.

At the first meeting of the session, held in the Faculty Hall, St. Vincent-street, on Oct. 30th, the following office-bearers were elected:—Honorary President: Sir John Williams, Bart., London. President: G. A. Turner, M.D. Senior Vice-President: Malcolm Black, M.D.; Junior Vice-President: J. Nigel Stark, M.B. Treasurer: Alexander Miller, L.R.C.P. & S. Secretary: Robert Jardine, M.D. Reporting Secretary: A. W. Russell, M.D. Pathologist: John Lindsay, M.B. Members of Council: Dr. Kelly, Dr. Cullen, Dr. Gunn, Dr. Jenkins, Dr. Reid, and Dr. Munro Kerr.

Glasgow Medico-Chirurgical Society.

At a meeting of this society on the 1st inst. Dr. Jas. A. Adams showed—(1) a woman on whom he had successfully performed excision of the pylorus for malignant disease; and (2) a patient who had suffered from a large ventral hernia which had been successfully operated on. Mr. A. E. Maylard showed—(1) a child on whom an inguinal colotomy had been performed for imperforate rectum; and (2) a boy who, as the result of a fall on the head, suffered from paralysis of the right upper limb and right facial spasm, these symptoms having been removed by trephining over the corresponding motor areas on the left side, with removal of a blood-clot which was situated between the dura mater and the bone.

Faculty of Physicians and Surgeons of Glasgow.

Dr. Bruce Goff has been re-elected President, Dr. James Dunlop Visitor, and Dr. James Finlayson Honorary Librarian to the Faculty.

Lifeboat Demonstration at Paisley.

An inaugural demonstration in aid of the Lifeboat Fund took place in Paisley on the 2nd inst., and some of the members of the medical profession took an energetic part in securing its success. Thus the chief marshal of the procession through the streets of the town was Mr. James Wallace, surgeon-dentist, who had for his principal assistants Dr. W. Wallace and Dr. R. Brownridge.

Aberdeen University.

At the meeting of the University Court held on Monday, Nov. 4th, the Lord Rector read a letter which he had received from Mr. C. W. Mitchell, who said he was pleased to hear that the University Court had decided to proceed with the North Tower of Marischal College. In his letter Mr. Mitchell quotes from a letter to Sir W. Geddes written by the late Dr. Mitchell, who said: "Lord Huntly, I believe, is endeavouring to raise a special fund of £20,000, and if £6000 of that amount can be collected soon, I would be prepared to contribute an additional £4000; further, if his lordship can increase his collection to £10,000, I will increase my subscription to £6000, thus making up the required £16,000 without appeal to the Government." "I now beg to confirm this offer," writes Mr. Mitchell, "subject to the consideration that your lordship's £6000 is collected by Jan. 1st, 1896, and the additional £4000 by May 1st." Lord Huntly said they were exceedingly grateful to Mr. C. W. Mitchell for so generously and nobly coming forward to homologate the wishes of his father, and he moved that the letters be referred to the executive committee with the request to take the necessary steps to raise the money and issue an appeal. This motion was seconded by Sir W. Geddes and agreed to.

Lord Provost Stewart's term of office has now expired, and as he is *ex officio* a member of the University Court this was his last meeting. The Lord Rector, on behalf of the members of the Court, expressed their regret at losing a member who took such a keen and practical interest in the progress of the University. At the same meeting the Court appointed to the Fordyce Lectureship in Agriculture Mr. James Wilson, M.A., B.Sc., who is at present Lecturer in Agriculture at the University College of Wales, Aberystwith. Mr. Wilson will take up duty on Jan. 1st next.

Nov. 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Annual Distribution of Prizes at the Royal College of Surgeons in Ireland.

ON Monday last the annual distribution of prizes for the session 1894–1895 took place in the hall of the college. Sir

W. Thornley Stoker, president of the college, who presided, addressed the students in eloquent terms and concluded by assuring them that he was in grave earnest when urging them to take enough relaxation in view of the severe routine of the medical education of to-day.

The Belfast Children's Hospitals' Staff Dinner.

On Tuesday, Oct. 29th, the medical and surgical staff (consulting and acting) of the Belfast Hospital for Sick Children, and of the Ulster Hospital for Women and Children, dined together at Thompson's Restaurant, Belfast. Including guests there were between thirty and forty present. Mr. John Fagan, F.R.C.S.I. (consulting surgeon to the Belfast Hospital for Sick Children), occupied the chair and proposed the special toast of the evening, "The Medical and Surgical Staffs of the two Children's Hospitals." He referred to the very happy feeling that existed between the two rival institutions, the ambition of both being to do the utmost possible good. He spoke of his own efforts in founding the first children's hospital in Belfast. Dr. McCaw of the Queen-street Hospital, and Dr. Calwell of the Mountpottinger Hospital, replied. A very pleasant programme of music was supplied by Dr. J. A. Lindsay, Dr. McCaw, Dr. McKisack, and Dr. Leslie.

Opening of the Medical Session.

The present winter session in the Belfast Medical School began on Oct. 29th at the college, when the professors commenced to lecture; and at the Royal Hospital on Thursday, Oct. 31st, when Dr. A. B. Mitchell, assistant surgeon, gave an inaugural address to the students on their duties, which was received with great favour. There was a very large attendance of the medical staff and of the students in the theatre, which has been enlarged, and which, when the new aseptic appliances are put in, will be in every respect an admirable operating-room.

The Notification of Infectious Diseases.

At a meeting of the Belfast Corporation, held on Nov. 1st, the Public Health Committee in their report again reaffirmed their opinion that the time has come when a thoroughly equipped hospital for the isolation and treatment of citizens suffering from infectious disease should be provided for the city of Belfast, and that such hospital should consist of not less than sixty beds, at an annual cost of £30 per bed (£1800). They were also in favour of the Notification of Infectious Diseases Act being adopted. The chairman of the Public Health Committee (Alderman Graham, M.D.) said that in Belfast 223 cases of infectious disease were notified during the last month (only a moiety of those actually occurring), and yet of these only 31 were treated in hospital. Of these cases 110 were scarlet fever, and yet only 10 of them were treated in hospital. The death-rate from zymotic diseases in Belfast was greater than in any other large town in the three kingdoms. Last year it was 4·10, while in Dublin it was only 2·4. The hospital, Dr. Graham thought, would not cost more than about £2700 each year. After considerable discussion, an amendment that the report be adopted, omitting the questions of the infectious hospital and of the Notification Act, was lost by 16 to 8 votes. The reasons which are advanced against the course recommended by the Public Health Committee are two: first, the increased expense, necessitating more taxation; and, secondly, the fact that the notification of infectious diseases would have to be made to the dispensary medical officers, who, in each of their districts, are the health officers, and not to the medical superintendent of the city. This arrangement, in case the Act is adopted, will have to be altered so that there will be one principal central health officer to whom notification can be made, and not a divided authority.

The Health of Belfast.

At the present time the health of the city of Belfast is very bad. The last reported death-rate was 23·1 per 1000, while last year at the same time it was only 17·7. In zymotic diseases, chest affections, and in the total from all causes, the deaths are largely in excess of the normal. The cases of infectious disease are more numerous than ever previously noted. Scarlet fever is very prevalent in every district of the town; the cases of typhoid fever are also very numerous, and measles has reappeared. With existing arrangements, neither isolation nor proper treatment of infectious disease can be enforced. The cases returned to the city medical officer of health are only those occurring amongst the poorer classes; he knows nothing as to the prevalence of infectious disease amongst the well-to-do people. Until the Notification of Infectious Diseases Act is put in force, and a new hospital built for the treatment of such cases, epidemics of scarlet fever or typhoid fever cannot possibly be dealt with in Belfast.

Night Nursing at the Ballycastle Workhouse.

The Ballycastle Board of Guardians having by fifteen votes to four declined to appoint a competent night-nurse, notwithstanding that their own medical officer reported that such an appointment was absolutely necessary, the Local Government Board wrote stating that if the guardians did not take the necessary steps to appoint a competent trained night-nurse they would issue a sealed order placing the management of the workhouse in the hands of law officers. As a result of this threat the board, on Nov. 2nd, decided to advertise for a trained nurse with a knowledge of midwifery, at a salary of £20 per annum, with rations and apartments.

A Hospital Sunday for Belfast.

At a meeting of clergymen representing the various religious denominations, held on Nov. 4th, it was decided that the last Sunday in November shall henceforth be held as Hospital Sunday, the day chosen for collection in the churches of Belfast on behalf of the Royal Hospital.

Larne Water-supply.

The engineer employed by the Larne town commissioners reports that the present supply from the Sallagh springs is quite ample if stored. The reservoir will hold 9,500,000 gallons, and its elevation will command the highest house in Larne. The engineer gives particulars of new works required and estimates the total cost at about £4200. The matter is not yet finally settled, but it is hoped that such an important seaside resort as Larne will soon be provided with an adequate water-supply.

Proposed Increase of Salary for the Visiting Medical Officers of the Cork Union Hospital.

Some months ago the guardians of the Cork Union decided on increasing the salaries of the visiting physicians to the Cork Union Hospital by £25 a year each, but the Local Government Board wrote refusing their consent. Last week the guardians unanimously passed a resolution expressing their entire approval of the manner in which the medical officers have discharged their duties and urging that in the interests of the ratepayers a salary of £125 a year ought to be paid to each of the medical gentlemen. It remains to be seen whether the members of the Local Government Board residing in Dublin will consider that they are the most competent judges as to what is best for the Cork ratepayers and for the sick poor in the Cork Union hospitals.

The Annual Dinner of the Cork Medico-Chirurgical Association.

The annual dinner of the members of this association was held at the Imperial Hotel on Saturday last, and was a great success. Dr. Giusani, president of the association, was in the chair. A number of toasts were proposed and responded to, and a very enjoyable evening was spent, music and song forming an important part of the programme. These social reunions do much to bind the members of the medical profession together, and just now union is everything to the Cork men.

Nov. 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Statistics of Hernia.

PROFESSOR BERGER of the Paris Faculty furnishes us[1] with the result of his examination of some 10,000 patients who applied for trusses at the Bureau Central from Feb. 4th, 1881, to Aug. 11th, 1884. The information thus gathered differs materially in many respects from that currently met with in standard works, and for which Malgaigne and the Truss Society of London are responsible. The applicants consisted of 7433 males and 2534 females (or three males to one female). Of the males of all ages affected with simple or multiple hernia 96 per cent. have the inguinal variety. Of 6220 hernia in the male, 4526 were double inguinal and 1042 simple inguinal (or 4·34 double to 1 single). This is in direct contradiction to all known statistics, and goes to prove

[1] French Surgical Congress, 1895.

Digitized by Google

that in the immense majority of cases inguinal hernia is a double process pursuing a synchronous or successive evolution on the two sides of the body in the same individual. Right inguinal herniæ are to left as 1·46 to 1. In bilateral inguinal hernia the right and left swellings are equal in volume to 42·2 per cent. in adults and 65·03 per cent. in adolescents, when irregularity exists the right is generally larger than the left. Many cases of budding (small) hernia escape observation, so much so that double hernia is even more common than would appear from the above figures. It is impossible in every case to assert the congenital origin of a hernia. In only 479 instances (216 above and 263 below fifteen years, 166 being complicated with testicular ectopia and forty-eight with other congenital malformations) was Professor Berger able to do this. The right side offers a manifest predisposition for the congenital form which is very rarely bilateral. The funicular variety (Birkett's "hernia into the funicular portion of the vaginal process of the peritoneum"), which is very frequent, is indistinguishable from acquired hernia. There are no certain means of distinguishing in the living subject direct inguinal from external oblique hernia. In females simple or double inguinal hernia alone, or associated with other varieties, occurs in 44·6 per cent.; the simple is about thrice more common than the double in infancy, but only twice as frequent in adolescence and maturity. Femoral hernia is rare in hernial males (6·6 per cent.), and it is in the majority of instances associated with other varieties, almost invariably the inguinal. Double is about as frequent as simple femoral hernia; right femoral is rather more commonly met with than the left. In females only 37·1 per cent. of hernial subjects have femoral hernia; *crural hernia in females is, therefore, less common than inguinal hernia* (1 to 1·35). In a certain number of cases the crural hernia escapes directly *in front of* the femoral vessels. The association of an inguinal hernia on one side, with a femoral hernia on the other, is sufficiently common, especially in the male (most commonly right femoral with left inguinal). Professor Berger has met with 207 examples in the male and only 19 in the female of uni- or bilateral co-existence of femoral and inguinal hernia. The most frequent combination is inguinal and femoral on one side with inguinal on the other (69 cases). Of herniæ in the male, 5·46 per cent. are *umbilical;* in the female, 27·34 per cent. Above fifteen years of age umbilical hernia in the male is almost always associated with other varieties (119 cases out of 134); below that age it co-exists with single or bilateral inguinal hernia in rather less than half the cases. In the woman umbilical hernia is invariably unaccompanied with other varieties. In the infant of either sex it is frequently associated with sub-umbilical eventration. Hernia through the linea alba and epigastric hernia are more commonly met with than is generally believed. Of the total number of herniæ, they represent 1·37 per cent. (Macready's figures are 0·096 per cent.). They are much more common in the male than in the female; they are sometimes multiple (Professor Berger has seen four superposed herniæ through the linea alba), and seem to be the remains of the aplasia of the linea alba which constitutes in the infant sub-umbilical eventration. Twenty-nine laparoceles in the female, and only 9 in the male, 1 case of obturator hernia, 2 of lumbar hernia, 4 hypogastric and 4 cicatricial herniæ make up, with the preceding, 13,483 herniæ noted in 7433 males of all ages; 2534 female subjects furnished only 3317 herniæ. The proportion of herniæ to the subjects of them are in the male sex 2 to 1, and in the female sex 1·3 to 1. Professor Berger calculates that in the Department of the Seine there is for every 14·9 males, for every 44·7 females, and for every 22·3 of all ages and sexes, 1 affected with hernia. In the male the frequency of simple inguinal hernia, very marked in the first five years of life, especially for the right side, diminishes rapidly up to thirty years, then increases up to a second maximum at fifty-five years. Double inguinal hernia, rare in infancy, increase rapidly in frequency from thirty to forty-five years, less rapidly from forty-five to sixty-five, and then decrease. Congenital inguinal hernia is extremely common during the first five years of life; they then diminish very rapidly in frequency, or are only seen associated with other varieties between thirty-five and fifty-five years. This is a proof that nearly all cases of congenital hernia disappear spontaneously or under the influence of a truss. The radical cure of these herniæ is, therefore, apart from exceptional cases, unjustifiable during the first four years of life. Femoral herniæ, exceptional in the male children in whom it always is simple, hardly begin to show themselves towards the age of thirty; their maximum of frequency is between sixty and seventy years. Simple umbilical hernia in the male is very common in the first year; from the fifth year onwards it practically disappears. Associated with other varieties, however, it is seen in middle and especially in advanced life. Epigastric hernia, rare in the male child, is hardly seen until after the age of thirty. Multiple herniæ are rare in the male child, less rare in adolescents, but frequent in adults, and especially in old men. In the female the dominant form in early years is the umbilical, which is extremely common; it disappears almost entirely between ten and thirty years, but becomes again more common after the latter period. Inguinal hernia increases in frequency between the ages of five and thirty, and both it and the crural variety from the latter age up to seventy, when both decrease rapidly. The majority of inguinal herniæ (in the male) appear first between forty and fifty years of age (congenital herniæ are not counted). Left inguinal herniæ appear later than right. Congenital inguinal herniæ make their appearance mostly very early in life; this may, however, be deferred to the first or second childhood, or even to puberty, or again to a later period. In the female inguinal hernia appears somewhat earlier than in the male (from thirty to thirty-five years). Femoral hernia appears most frequently in woman between the ages of thirty-five and forty-five, in man between forty and forty-five, the maximum of frequency in woman corresponding, as for inguinal and a certain number of umbilical herniæ, to the period of sexual activity. Umbilical hernia is congenital, or appears during the first year in nearly all cases in males, and in the great majority in females. In woman, a large proportion appearing after thirty years, it is a question whether these subjects are not congenitally affected, and whether pregnancy has not been the aggravating cause. Professor Berger has discovered that the average age at which hernia first appears in individuals affected with multiple or double varieties (especially double inguinal) is much more advanced than is the case in the subjects of simple hernia. This would seem to prove that simple hernia is more often congenital in origin, whilst the double or multiple are acquired. The interval (very variable) between the appearance of two herniæ in the same subject is longer for congenital inguinal herniæ than for all other varieties of hernia. In acquired inguinal and in double femoral hernia the interval hardly exceeds ten years; in a good third of the cases the bilateral herniæ development is simultaneous. Hereditary influence was noted in 2079 out of 7542 cases. This hereditary predisposition is especially homosexual (from father to sons and from mothers to daughters). In families in which the hernial heredity was noted, 1 in 3, or even 1 in 2, members had hernia, thus demonstrating the existence of hernial families. The influence of occupation in the production of hernia is undoubted (manual labour and, also, work in the erect posture). Certain sedentary occupations requiring a forward inclination of the body and repeated efforts predispose particularly to hernia. Parturition favours hernia, as is shown by its enormous frequency in multiparæ. It is especially after labour, rather than during pregnancy, that hernia appears, although some already existing herniæ only then increase in volume. Diseases of the respiratory organs favour hernia; urinary affections and habitual constipation have hardly any influence. Amongst occasional causes unusual muscular effort whilst in a *false* position or whilst carrying a burden is prominent. ¡Cicatricial hernia are, according to Professor Berger, rarely seen. Irreducible hernia is comparatively rare (1 in 28); it is commoner in femoral than in inguinal, in umbilical and epigastric than in femoral, and more frequent in woman than in man. It is less commonly seen in herniæ subjected to the pressure of a truss than in others. Functional troubles (colic, local pain) are observed in cases of voluminous and partially irreducible herniæ. Dyspeptic symptoms are very frequent in male subjects with epigastric and in female subjects with umbilical ruptures. Of 10,000 hernial subjects of all ages and both sexes 3·31 per cent. had suffered at one time or another from serious complications connected with the hernia. These complications were more frequent in the female (5·34 per cent.) than in the male (2·46 per cent.), in femoral hernia (6·45 per cent.) than in umbilical (1·91 per cent.) or inguinal (1·45 per cent.). Of these complications, strangulation (serious 250 cases, mild 43 cases) was the most common. The wearing of a truss appears to exercise no

Digitized by Google

influence one way or the other in inducing the appearance of complications which are liable to recur. They are more frequent in old than in recent hernise; they are more serious in woman than in man, in femoral than in other varieties. In more than one-half of the cases of strangulated femoral hernia in the woman kelotomy had to be resorted to. Thus, while females are much less liable to hernia than males, complications are more frequent, and these complications are more serious in their nature. *This is an important point in life assurance reports.* Strangulated hernia, with or without operation, does not, however, appear to involve a high mortality (about 1 per cent.). There is, therefore, one condition without which the operation for the radical cure of hernia is unjustifiable—and that is its innocuousness. The foregoing *résumé* of a most valuable paper is, unfortunately, rather diffuse. The vast importance of the subject is, I imagine, a sufficient excuse for this long-windedness, and the profession owes a debt of gratitude to Professor Berger for his painstaking researches.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Sixth Congress of Internal Medicine.

By a not altogether desirable arrangement the forenoon sitting on Oct. 23rd was devoted, not to the discussion of the report on Sero-therapy—an account of which was published in the last issue of THE LANCET,—but to the reading of the paper by Professors De Renzi and Reale on the Decline of Nutrition in the Human Economy. Professor De Renzi, who holds the chair of Clinical Medicine in the Neapolitan school, took up the first part of the subject, and after an elaborate and interesting exposition he came to the conclusion that there is a group of maladies presenting characters in common—characters hitherto attributed to a decline, slackening, or falling off (*rallentamento*) in metabolism. But the genesis of these maladies—at least, in some cases—cannot unreservedly be ascribed to this *rallentamento*. With more probability must we seek their cause in the diminution of the oxidising processes and the position as regards aeration (*posizione aerobia*) of the tissues. By such perturbation in nutrition are developed acid products and substances peculiarly toxic, above all in the nervous system. A character common to nervous disturbances in these affections is their manifesting themselves mainly in the night, when, by the patient's reposing in bed, there is a considerable diminution in the consumption of oxygen and in the elimination of carbonic acid. The principal remedy in such cases consists in the diminution of food and in exercise, while benefit may be derived from a special alimentation and from diverse modes of treatment, chemical and physical. But it is not improbable that with the discovery of oxidised *media* or ferments extracted from the tissues we may attain a rapid and complete cure of these maladies. The remainder of the subject was dealt with by Professor Reale, assistant to Professor de Renzi. His positions were these: The received doctrine of nutrition is based on two orders of facts, first, those which have regard to the organic equilibrium, and secondly, those which concern the bio-chemical processes carried on in the *vie intime* of the tissues. Research into the organic equilibrium of the healthy subject is far advanced as compared with that into the unhealthy or diseased, which latter, indeed, can hardly be called "initiated." The former must be our main guide in studying the alterations in the material exchange (metabolism). Experimental investigation into the *vie intime* of the animal tissues establishes the existence of a *funzione anarrobia* which is not in opposition to the data of the pathology of metabolism. Decline of nutrition is not manifested under one form only. Diminished energy of exchange in the cellular elements, strictly so called, is found only in polysarcia adiposa. It is wanting in all the other affections commonly held as kindred, diabetes included. In these latter we are confronted, as a characteristic note, with the fact that a part of the material of decomposition abandons the tissues incompletely oxidised. The appearance and the augmented elimination of some principles really indicate an alteration in the intimate nutritive exchanges of the tissues, and peculiarly in the deficiency of organic oxidation. Recent studies diminish the value hitherto attached to uric acid, withholding confirmation from its claim to be a product of the decomposition of albumin; but not so for oxalic acid, to which the same studies revindicate the importance originally assigned to it. To determine the degree of insufficiency of the oxidative products (*prodotti ossidativi*) in the organism we have at length a sound method—by comparative researches on individuals themselves in determining the relation between the neutral sulphur (*solfo neutro*) and the acid sulphur (*solfo acido*) of the urine. This closed the forenoon sitting. After luncheon began the discussion of the previous day's report on Sero-therapy. Professors Guiffré, Petrone, Fazio, and Senise made diverse criticisms, agreeing, however, that those who had watched closely the patients treated with the Maragliano serum found the results surprisingly favourable. After this the discussion took a theoretical turn and brought Professor Foà to his feet in reply. Admitting that sero-therapy was still on its trial, and that in tuberculosis particularly the laboratory has much to prove, while the clinique is by no means entirely convincing, he maintained that the therapeutic art, with its new agent, was on the right track and the desired goal not far distant. Professor Maragliano next availed himself of his right to reply, and said that as a clinician he reduced his claim to the narrow compass of being able to prove that his serum is a true adjuvant to the treatment of tuberculosis—always subordinating the seductive findings of the laboratory to the test of tests—that of the bedside. By permission of the President the Neapolitan Professor von Schrön was allowed to speak in supplement to Professor Maragliano. The tenour of his remarks was on the whole favourable to the serum in tuberculosis. Too early in the day for a definite judgment, we may yet claim, he thought, for the Maragliano agent an increase in the number of cases of tuberculosis in the primary stage. The forenoon sitting of the 24th was occupied with miscellaneous subjects, the first of which, as handled by Dr. Queirolo and Dr. Caramelli of Pisa, on the Ictus Cordis, was especially interesting. Cognate to this, and equally well discussed, was the paper of Dr. Bonetti of Padua on the Morphology of the Heart, while Dr. Gay of Pinerolo read a useful monograph on Infantile Paralysis. The afternoon witnessed some "slaughter of the innocents" in the suppression or perfunctory hearing of other papers, some of which yielded in interest and expository power to none of the preceding ones. The sittings of the 25th were similar in their tenour, the papers most likely to form the chief attraction of the official "Atti" (proceedings) being Professor Lucatello's on Puncture of the Liver with a Diagnostic Aim, Dr. Pittarelli's Studi Urologici, and Dr. Mennella's on the Treatment of Anæmia and on Velocipedism. Dr. Baccelli (President), *à propos* of a paper by Professor Reale on Nitrate of Silver in the Therapeutics of the Stomach, described some cases of follicular disease of the pylorus in which he had found the nitrate wholly successful. The Congress was thereafter closed by an eloquent discourse from Professor Rummo, who, in the absence of Dr. Baccelli, was called to the presidential chair; and preparations for its successor, the seventh, were made by the appointment of an organising committee, of which Dr. Baccelli was re-elected president, Professors Mirri and De Renzi vice-presidents, Professor Maragliano secretary, and Dr. Rossoni treasurer.

A Warning to Tourists.

Italian vineyards have of late years been heavily visited by the peronospora, and to counteract it sulphate of copper has been freely powdered over the stems, the shoots, the leaves, and even the grapes themselves. In consequence the vine and its product have become so charged with copper as to be a fertile source of poisoning. So frequently has this been the case that in some communes the sanitary authority prohibits the use of vine-leaves as wrappages for butter, while, as to the grapes themselves, so favourite an adjunct to dessert, they have proved in many instances positively dangerous to the consumer. Gastro-intestinal irritation in every degree up to active poisoning is quite a common sequela to their consumption, so much so indeed as to add a new terror to the sojourner in *pension* and hotel. In the better class of these houses the grapes are well washed before being put upon the table, and even then they are none the worse for an extra dip or two in the finger-glass, or, failing that, in the tumbler. In Italy, indeed, where medieval uncleanliness pervades even city life, it is always well to wash one's fruit in this way before tasting it at dinner—a glimpse of the hands through which it has previously passed

Digitized by Google

sufficing to justify the precaution. But in the matter of grapes the powdering of vine-leaf and fruit with cupric sulphate makes previous washing of them doubly necessary on the consumer's part, if he would minimise the risk of severe colic or worse. Nor is it from the grape alone that the danger of copper poisoning is a real one in Italian hotels. The other day in the Neapolitan territory, on the opening of a new railway line, I read of a banquet in honour of the occasion, at which between thirty and forty of the company's employés sat down. Every one of them before regaining his home was the same evening attacked with the severest abdominal pains all too traceable, it is said, to poisoning due to verdigris adhering to the culinary pots and pans. From the same cause, as opportunely reported in THE LANCET not so many months ago, some forty patients in the great hospital of the Santa Maria Nuova in Florence were seized with excruciating tenesmus, and, as there was a "cholera shadow" on the wing, the alarm so occasioned extended beyond the specially visited ward and threw the whole establishment and neighbourhood into not unjustifiable panic. Medical inquiry soon set the matter at rest, however, having ascertained that the culinary apparatus in use at the hospital was foul with verdigris, the irritant properties of which had been liberated in unusual proportion by some accidental ingredient employed in cooking. Italian winter cities are apt to grumble if for a season the travelling world gives them a wide berth. Does it never occur to them that they themselves are often more prolific of deterrents than of attractions, and that a more hospitable view of the "foreign import" than as a source of revenue should prescribe on their part a little more attention to sanitary and culinary law? They may look on the stranger within their gates as a "goose"—but then he is a goose that lays "golden eggs"; and their wisest policy is to keep him in good case, to do anything to him but "kill" him.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Etiology of Gout.

HORBACZEWSKI'S opinion that there is a constant proportion between the number of white corpuscles in the blood and the amount of uric acid excreted has been refuted by Dr. Kolisch, who stated at a meeting of the Vienna Medical Society that from the nuclein there originate albumin and nucleinic acid, the latter again forming phosphoric acid and an unknown substance which transforms itself into uric acid and the so-called alloxur bases. As long as the kidneys are sound all the products of the decomposed nuclein are excreted as uric acid, but in renal disease the formation of uric acid is incomplete, and in its place there occur alloxin bases. There is a certain connexion between true gout and some forms of renal atrophy, but the nature of this relation is not yet cleared up. The analogy of these diseases of the kidneys with those occurring in lead poisoning, and the further fact that lead may play a part in the etiology of gout, support the theory of the toxic nature of gout. Dr. Kolisch has succeeded in proving experimentally that there is an increase of alloxur bases in the urine of gouty patients, and he therefore supposes these substances to be the cause of gout. During normal action of the kidneys the greater part of the alloxur bases is excreted as uric acid; but when the structures which form uric acid are enfeebled there is an increased excretion of alloxur bases, with concomitant toxic effects. The most probable explanation of the uric acid diathesis is the existence of a congenital inherited tendency to an abnormal decomposition of nuclein. The substances thus originating do not impair the kidneys rapidly, for at first their toxic effect is counteracted, but in the course of years the kidneys become disordered, lose their power of counteracting the toxic effects of the nuclein products, and the health of the individual gives way. A fit of gout is, therefore, due to an overcharging of the organism with the products of the decomposed nucleins. Gout cannot be treated specifically, for there is no remedy which can diminish the inherited tendency to the decomposition of nuclein; but the patient must avoid all that is likely to increase the quantity of these products or to injure the kidneys. The beneficial effect of the alkaline treatment is probably due to the fact that by it the energy of the kidneys is increased. There is no ground for reducing the amount of albuminous food with the exception of tissues containing nuclein. Boiled meat is to be allowed, and also milk, eggs, and fat. Gout may be easily diagnosed, especially in children, by the so-called perinuclear basophilia on microscopical examination of the blood or by the occurrence of alloxur bases.

Pigmentation of the Skin after the Use of Arsenic.

At the last meeting of the Vienna Medical Society Dr Schlesinger exhibited a patient who had been taking Fowler's solution on account of a tumour in the right arm-pit, and after three weeks' use of it he noticed a discolouration of the skin. Pigmentation of the skin due to the use of arsenic was first observed some thirty years ago in a case of psoriasis. As a rule it commences gradually, and there is no pigmentation of the mucous membranes—a circumstance which distinguishes these cases from Addison's disease and argyria. The total quantity of arsenious acid taken by the patient amounted to 0·464 gramme (about 7 grains). Mathieu has published a case in which a patient took arsenic for ten years without sustaining any harm, but discolouration of the skin occurred when the daily dose was increased. Dr. Schlesinger advocated the use of arsenic in cases of lymphosarcoma, for the patient showed no other ill-effects attributable to the arsenic, and there was perceptible retrogression of the tumour.

Riotous Behaviour in the University.

Some days ago the University was the scene of disorders which have not failed to cause a general sensation. According to an old custom all the students' societies were present at the inauguration of the Rector Magnificus, which is celebrated with great pomp. But there is an old feud between those students who fight duels and those who refuse to do so, the latter, as true Catholics, condemning the practice from the religious point of view. Nevertheless, they appeared in the *aula* of the University with sabres, a proceeding which caused a great commotion, for the so-called "fighting" students tried to compel them to leave, and a scuffle ensued; but quiet was restored by the intervention of the Pro-Rector, who exhorted the students to respect the dignity of their *alma mater*. Charges against eighteen students have been laid before the Senate of the University, and the Rector has prohibited the so-called "Bummel," a promenade in the *aula*, which takes place every Saturday.

The Dermatological Congress at Gratz.

Tertiary syphilis was one of the subjects discussed at this gathering. Dr. Caspary (Königsberg) said that statistics have not proved that it is prevented by the intermittent treatment proposed by Fournier. He recommends the so-called symptomatic treatment in slight cases of secondary syphilis, and makes use of Fournier's method in grave secondary and tertiary forms. Dr. Meisser (Breslau) said that the omission of energetic mercurial treatment during the early stage of syphilis seems to be the most important factor in the etiology of tertiary symptoms. Mercurial treatment should be commenced as soon as syphilis is satisfactorily diagnosed, and in this case it sometimes happens that no relapse occurs during ten years. A proof of the etiological relations between neglected or insufficient mercurial treatment during the early stage of the disease and the eventual occurrence of tertiary manifestations is the prevalence of endemic syphilis in localities where it is not methodically treated.

Professor Vogl.

The Pharmaceutical Society of Great Britain has presented the Hanbury Medal to Dr. August Vogl, the Professor of Pharmacology. This is the eighth award of this medal, which was presented in 1881 to Flückiger, in 1883 to John Elliot Howard, in 1885 to Dragendorff, in 1887 to Dymok, in 1889 to Plaichon, in 1891 to Hesse, and in 1893 to Maish.

Medical Fees.

The country practitioners of Lower Austria are at present discussing the question of medical fees. Dr. Läufer has proposed the following tariff: advice at the house of the physician, 8*d.*; first visit to a patient's house, 1*s.* 3*d.*; all subsequent visits, 1*s.*; night visits, 2*s.* 6*d.*; a subcutaneous injection, 10*d.*; an injection with antitoxin, 3*s.* 4*d.*; putting up fractures, 9*s.* 10*d.*; herniotomy or tracheotomy, £1 5*s.*; amputation, £1 15*s.*; induction of premature labour, 16*s.*; and microscopical examination for bacteria, 3*s.* 4*d.* If the patient sends for another practitioner the one already in

Digitized by Google

attendance is to be informed of the fact, and when a patient desires to change his medical adviser the practitioner called in is not to undertake the case unless his predecessor has been paid.

Cholera in Galicia.

During last week 57 cases of cholera, with 32 deaths, have been reported from the districts of Tarnopol, Czortkow, Husiatyn, Kamionka, and Przemysl, making a total of 196 cases with 123 deaths since the commencement of the outbreak. In the preceding week there were 19 cases and 18 deaths.

Nov. 3rd.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera News.

DURING the last twenty-four hours 7 new cases and 2 deaths have been reported from the infected districts. Since cholera was first officially declared on Oct. 13th there have now been 266 cases discovered, including 148 deaths. Allowing for the probable existence of a few mild cases which have not been reported, these numbers give a mortality of about 50 per cent. The districts may be geographically divided into four: Damietta and its suburbs have furnished 59 cases and 36 deaths, the medical officer of the district being Dr. Pinching; in Menzala and its neighbourhood there have been 167 cases and 94 deaths, and on the canal between Mansoura and Menzala 19 cases and 11 deaths, all being under the inspection of Dr. Graham, who has been lent for this work by the Egyptian Army; Fakus, a small town in another province, has furnished 21 cases and 7 deaths, and the whole of this neighbourhood is under Mr. H. Milton. Dr. Keatinge, moreover, has been despatched to Mansoura to carry out sanitary reforms begun there last week by Dr. Sandwith. Each of these medical men has a competent police officer attached to him and as many native medical men as he wants. It seems to be admitted without argument by all nationalities that it is only Englishmen to whom the energetic work of stamping out disease can be entrusted. It is satisfactory to see that cholera has as yet not spread beyond the places where it was originally discovered after active search. The abominations of land quarantine and sanitary cordons are not being used, but a constant series of inspections of all barges and their passengers has been instituted on the Nile and canals between Cairo and the infected spots. Dr. Rogers Pasha returned to Cairo from England a week ago and has organised a system which ought to be sufficient to eradicate the existing bacilli. His greatest ally is the Nile in flood, the current of which flows in the direction exactly opposite to that of the cholera march.

Precautions at Mansoura.

English readers may like to know some of the principal points which are likely to occupy a sanitary reformer in an Egyptian town threatened with cholera. Mansoura has a population occasionally reckoned at 40,000, and sometimes at 60,000, but with no proper sanitary inspection. There is an attempt at a town council, but it consists entirely of natives and is quite useless. The drinking-water all comes from the Nile, and instead of being taken from stagnant pools near fouled banks must be drawn from the current itself a few yards out. Rafts for this purpose were made in two days, and every drinking place and the whole bank were placed under constant inspection. This was a very popular measure in the eyes of even the natives. The streets, the markets, and stables were all ill kept, and the organisation for scavenging existed only on paper. It is chiefly for this kind of work that young English police officers are admirable. A sanitary commission already exists for the town consisting entirely of unintelligent natives, so an attempt was made to leaven it by inducing the Mudir to add to it two European merchants. Most mosques have a public latrine attached to them, and all these have to be carefully inspected and the cesspools emptied out. Arrangements had to be made for both the sick and the dead in the event of cholera occurring either among the natives or among Europeans. This matter becomes complicated when one remembers that every European's home is sacred to him and to his Consular authority. Woe betide the Anglo-Egyptian if he happens to "infringe the domicile" of a French Syrian. A supply of disinfectants had to be summoned from Cairo to replenish the hospital stores, and all the quicklime of the town was bought up by the Mudir. Medicine for possible cases of diarrhœa was distributed gratis throughout the town, and huts for 36 patients were rapidly erected to make the nucleus of an infectious hospital to the south of the general hospital. The public baths, the prison, and the schools all had to be examined and reported upon, and certain salutary changes effected. It is impossible in a short space to describe the manifold duties of the moment, and it is quite possible that even better work is now going on in other towns and villages. The natives work extremely well under Englishmen, though they do absolutely nothing if left alone. They say themselves that they are contented with merely giving orders, whereas the Englishman goes the next day to see if his orders have been carried out.

Cairo, Oct. 30th.

Obituary.

RICHARD BASIL MORLEY, L.R.C.P., L.R.C.S. EDIN.

THE news of the sudden death of Mr. Morley at the early age of forty-three when in apparently perfect health came as a painful shock to his many friends in Leeds. He was the son of the late George Morley, for many years one of the leading practitioners in Leeds and lecturer on forensic medicine at the Leeds School of Medicine. Mr. Basil Morley began his medical career comparatively late in life. Of genuinely scientific and speculative tastes, he had found business uncongenial, and he entered as a student of the Leeds School of Medicine, where he was greatly distinguished amongst the men of his year in winning honours and prizes. He qualified in 1883 and became resident officer at the Leeds Public Dispensary. He then began practice at Chapel Allerton, Leeds, where for nine years he had a name for thoroughness of work and kindliness to the poor. Mr. Morley was always a lover of nature, and delighted especially in country work. He was a man of such an unusually quiet and retiring disposition that comparatively few of his professional brethren knew the breadth of his mental endowments or the force and depth of his personal character. To his friends and patients he was greatly endeared by his kindly and genial disposition and his gentle and generous heart. The cause of his death was cardiac syncope. He had ridden out three miles into the country upon a bicycle to visit a poor patient, and, sitting by her bedside, he fell forwards suddenly from his chair and almost immediately expired. The very large number of mourners who filled the churchyard at his funeral testified to the public esteem which he had won in his short professional life.

JAMES MATHEWS, L.R.C.P., L.R.C.S. EDIN., L.A.H. DUBL.

PUBLIC feeling in Cavan has been deeply moved by the death of Mr. James Mathews, who passed away on Oct. 20th after a short illness. The deceased gentleman's blameless life, gracious manner, and devotion to the interests of his patients, united in procuring for him an enviable position in popular esteem. He came of a talented family, many members of which as priests have devoted themselves to the spiritual welfare of their fellow creatures, and his natural abilities found congenial exercise in the acquisition of professional knowledge during the long period which has elapsed since he entered into practice in 1860. On Oct. 22nd a solemn mass for the dead was said in Cavan Cathedral and the interment took place in the burial ground at Laragh in presence of a very large assemblage. Mr. Mathews leaves a sorrowing widow and family.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Otto Janicke, chief medical officer of the Augusta Hospital, Breslau, after a short illness. He was a comparatively young man and was greatly esteemed for his skill in operative surgery.—Dr. Hermann Fischer of Berlin, formerly Professor Langenbeck's assistant. He, however, gave up surgery and practised as a homœopath.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of Fellows and Members of the Royal College of Surgeons of England was held on Thursday afternoon in the Hall in Lincoln's-inn-fields, London. Mr. CHRISTOPHER HEATH presided.

The Council's Report.

The PRESIDENT formally presented the annual report from the Council, extracts from which have already been published. In doing so he gave a welcome to those attending the meeting, and ventured to remind them that they, the Fellows and Members, were the corporation of the College. That he found was a fact that was very often overlooked.

Surgeon-Major INCE moved: "That the Fellows and Members here assembled in annual meeting desire to thank the Council for the interesting and important report now presented, and particularly to express their approval of the new By-laws, Sections 4 and 16, and of the Regulations of the Council, Section 25, relating to the meetings of the Fellows and Members of the College." He desired, he said, to express sympathy with their esteemed secretary.

The PRESIDENT asked Surgeon-Major Ince to confine himself to the business and be as brief as possible.

Surgeon-Major INCE said he apologised. This, he went on to say, was the third time he had moved a motion of the kind. He trusted it would be the last, because he thought the motion should come from a Fellow rather than a Member. The motion was very necessary and it was desirable. By accepting such a motion the Council conceded to them the privilege of criticising their administration of the affairs of the College, and if these annual meetings were continued, they should in the course of time acquire a prescriptive right to have annual meetings. That was an important reason why a motion of this kind should be brought before the meeting. Surgeon-Major Ince was proceeding to raise an educational question when the PRESIDENT again interrupted him, asking him to confine himself to the motion.

Surgeon-Major INCE thereupon formally moved the resolution.

Mr. GANT seconded.

Mr. GEORGE BROWN did not know how they should accept such a motion. They did not know what the by-laws referred to in it were, and he was quite sure the Council did not require a formal expression of the Members' and Fellows' approbation. They should drop this and go on with the more important business on the paper. He moved the previous question.

Mr. BRINDLEY JAMES seconded this amendment.

The PRESIDENT at once put the proposal to the meeting, and the previous question was carried by a majority.

Reform in the College.

Mr. JOSEPH SMITH rose to move: "That this meeting requests the Council to take steps to obtain an amended Charter which shall contain the following provisions: (*a*) that no alteration in the constitution and external relations of the College shall be effected without the consent of the body corporate convened to discuss such alterations; (*b*) that the present annual general meeting be made statutory, and that the report of the Council shall be submitted for formal adoption; (*c*) that the number of the Council be increased to thirty-two, and that eight of these, who may be Members, shall be elected by the Members only, provided always that no Member who has not been a Member for twenty years shall be eligible for a seat on the Council." He said it was continually being asked: Who were the men who were agitating for reform? Where did they come from? What was their standing? Members of the Council were continually harping on this string, suggesting that those who asked for reform were nonentities. But what he had to tell those members of Council in reply was that for the last ten years resolutions asking for reform had been carried in that building by crowded meetings from all parts of England. It did not matter what was the membership of their association, whether it numbered 5, 50, or 5000. They spoke in the name of those men who had met for years and years, and in the name of 5000 men whose signatures were attached to a petition which at present lay at the Home Office, asking what they were demanding here. Yet they were held to be an insignificant body.

The PRESIDENT suggested that the proposal should be taken in sections.

Mr. SMITH said he wished the proposal to go forward as a single resolution, but he was in the hands of the chair.

The PRESIDENT thought it advisable to proceed in sections.

Mr. SMITH formally moved (*a*) as a section.

This was seconded by Mr. DICKINSON, and unanimously carried.

Mr. SMITH, in next moving Section (*b*), said they held this and like meetings subject to their good behaviour. It was quite open for the Council to shut the door in their faces, telling the Members and Fellows that they did not want them.

Mr. DICKINSON seconded, and this section also was unanimously adopted.

Mr. SMITH said that Section (*c*) was the *crux* of the resolution. He believed the membership of the College was 14,000 or 15,000, and all they asked for was a representation of eight, who might be Members or might be Fellows. At present the Members had absolutely no control over the affairs of the College. It all lay in the hands of the Fellows, who numbered only about eleven hundred. Those who asked for reform did not ask for any of the privileges of the Fellows, but they fully believed that if the Members were represented on the Council that body would be very much strengthened. Their chairman of to-day was not the President of the College of Surgeons.

The PRESIDENT: I beg pardon.

Mr. SMITH: No; you are only elected by the Fellows; you are the President of the Fellows. How much greater would be your power and influence if you were elected by Members in addition to Fellows.

Mr. DICKINSON seconded.

The motion was supported by Dr. ALDERSON, Mr. TIMOTHY HOLMES, and Mr. CRAVEN, and on being put to the vote was carried, there being only two dissentients.

Admission of Women.

The PRESIDENT stated that the Council desired to afford the Fellows and Members present the opportunity of expressing their views upon the question of the admission of women to the examination for the diploma of Member. The matter came before them in this way. The Council had received a letter from Mrs. Garrett Anderson asking that the students of the London School of Medicine for Women should be admitted to the examination of the College. The question was a very important and vital one, and, while having no proposal to make, the Council wished to have the benefit of the meeting's views on the subject.

Mr. GEORGE BROWN said everyone had sympathy with ladies who were studying for their noble profession, but he could not conceive any good reason for admitting them to Membership of the Royal College of Surgeons. They could get diplomas elsewhere, as all the universities of the United Kingdom were open to them.

Mr. JOSEPH SMITH, agreeing with Mr. Brown, moved: "So many portals are open to women to obtain a surgical diploma, it is not expedient that this College should open its doors to admit women to examination for the diploma of the College."

Mr. BRINDLEY JAMES seconded this motion. He did not wish the College to be under petticoat government. He was afraid that if women were admitted Members of the College they would also be admitted to the higher positions, to the Fellowship and to the membership of the Council. As a matter of fact, he for one objected altogether to women getting into the medical profession, and if they were to obtain diplomas at all he would prefer that they should get them from the Royal College of Physicians.

Mr. CLEMENT LUCAS moved as an amendment that in the opinion of this meeting women should be admitted to the diploma of this College, but he did not think the Members and Fellows of the Royal College of Surgeons should be frightened at the competition of women, and he hoped that no petty feelings would prevent this meeting from doing the women justice.

Mr. NORTON seconded the motion. He saw no reason why women should be excluded.

Dr. R. BARNES, in supporting the original motion, pointed out that surgery was the highest grade of the profession. It demanded the highest talent, skill, and powers, and these did not belong to women.

Dr. ALDERSON did not think it would give strength to the

Digitized by Google

College to admit women to the best surgical diploma in the world.

The amendment was then put to the meeting and rejected by 58 votes to 48. On the original proposal being next put as a substantive resolution, 58 voted for it and 39 against it.

A vote of thanks to the President brought the proceedings to a close.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. Weintrand, late of Berlin, who was recently appointed to the post of Chief Medical Officer of the Policlinic, has been recognised by the University as *privat-docent.*—*Budapest:* Dr. Herczel has been recognised as *privat-docent* in Surgery.—*Bonn:* Dr. A. Partheil, first assistant in the Marburg Pharmaceutical Institute, has been appointed Extraordinary Professor of Pharmacy.—*Gottingen:* The chair of Surgery, vacated by Professor König's translation to Berlin, is expected to be offered to Dr. Riedel of Jena.—*Marburg:* Dr. Ostmann of Königsberg has been appointed Extraordinary Professor of Otology in succession to Professor Barth, who goes to Breslau.—*Tubingen:* Dr. Lenhossek of Würzburg has been appointed Prosector in the Anatomical Institute in succession to Dr. Freriep, who has been promoted to the Professorship of Anatomy.—*Wurzburg:* Dr. Johannes Sobotta, assistant in the Berlin Anatomical Institute, has been appointed Prosector in place of Dr. Lenhossek.

DIPHTHERIA AT LEATHERHEAD.—The Leatherhead urban district council is unable to account for an epidemic of diphtheria. Mr. E. L. Jacobs, the medical officer of health, has reported to a recent meeting of the body in question that he is unable to arrive at any definite conclusion as to its cause. At one of the infant schools a few cases of sore-throat have been noted, and it is suggested that a slight unrecognised diphtheritic attack in some of these cases may have been the cause. Dr. Thorne Thorne, writing to Mr. Jacobs, expressed an opinion that the impurity of the water-supply had never caused the disease, there being, indeed, he said, abundance of evidence in the opposite direction. At the same meeting of the council more cases of scarlet fever were reported and some water-supplies stated to be unfit for domestic use. No action was, however, taken in regard to the latter.

DIPHTHERIA IN LONDON.—The condition of the metropolis as regards diphtheria is even worse than we reported last week. In the last week of October the registered death-rate fell to 61 from the 76 of the previous week, and though the 76 deaths were a rise in one week from 56, it was hoped that the high total was exceptional. These hopes were, however, dissipated by the death-roll of last week, when the registered deaths from diphtheria in London again rose to over 70—being 72—and were 34 in excess of the corrected decennial average of the forty-fourth week of the years 1885-94. Whilst the heaviest number of deaths belonging to any one sanitary area occurred in Greenwich, there was also a large amount of the disease in the north of the metropolis, especially in Islington, and even further afield. The number of removals continues to be ridiculously small in comparison with the new cases coming to light, the removals of last week being slightly over 100, and in the previous week only 115 out of some 320 fresh cases. On Saturday last the patients remaining under treatment in the London hospitals numbered 671, practically the same as in recent weeks. It is evident that as vacant beds are reported they are filled up at once, but this by no means suffices for the amount of disease newly arising. In greater London the deaths were last week again over 20 in number, occurring most numerously in West Ham, in Hornsey, and in Willesden. In all these districts, especially the former, the disease seems to be established; and in Essex we hear of it as far away as Larkfield, near Maidstone, where schools have had to be closed, and several deaths are reported. During last quarter there were 1805 deaths from diphtheria in England and Wales, and of these 605 occurred in London—that is, one-third of the total number of deaths in but one-seventh of the population. In the county of Essex the death-rate from diphtheria was 64 per 10,000 of population, as against 24 in the country at large; and in the town of West Ham it was as high as 85. In Willesden, Hornsey, and also in several home counties, in addition to Essex, the fatality was exceptionally high, though there were counties with absolutely no deaths from the disease during the entire quarter.

SUPERANNUATION ALLOWANCE.—Mr. Thomas G. Anthony, M.R.C.S., late medical officer and public vaccinator the Tredegar district and workhouse, Bedwellty union, has been granted a superannuation allowance of £80 per annum.

A SAD CATASTROPHE.—A fatal accident occurred on Friday last at Chepstow to Mr. Arthur Snead Lawrence, late a student of Middlesex Hospital, the eldest son of Mr. A. G. Lawrence, M.D., J.P., of Chepstow. The deceased gentleman, who had very recently obtained his double qualification at the Conjoint Board, was thrown from his horse and sustained a fracture of the skull, to which injury after thirty hours' unconsciousness, he succumbed on Saturday evening.

SUSSEX COUNTY HOSPITAL.—An influential public meeting was held in the Royal Pavilion, Brighton, on Oct. 31st, for the purpose of calling attention to the financial position of the Sussex County Hospital, and devising means for increasing its income. The Earl of Ashburnham, who presided, said that the hospital had claims on the generosity of the public far beyond the limits of Brighton, the town being a favourite resort of visitors from all parts of the country. The hospital was very embarrassed in a financial sense, a balance of £295 being due to the treasurers on Dec. 31st, 1894, and a large legacy recently bequeathed having become the subject of a law suit. Repairs of the present building and very considerable structural improvements were absolutely necessary, some of these being sanitary towers estimated to cost about £2900; additional accommodation for the nurses, about £4850; a new out-patients' department, about £4800; a hydraulic lift about £600; and a new operating room about £1200. The total estimated cost of these indispensable buildings was £25,000, and a resolution was passed to the effect that every effort would be made to raise that amount.

NEWTON ABBOT WORKHOUSE.—On Wednesday last Dr. James Culross, medical officer of Newton Abbot District and Workhouse, presented a quarterly report to the Newton Abbot Board of Guardians, in which he advisedly deviates from the usual course in such reports, and takes a survey of the condition of the workhouse and of the progress that has been made during the past twelve months in the institution. After referring to the improvements that have taken place on all sides—improvements which it must be a source of gratification to the guardians to observe have been productive of much good—Dr. Culross calls attention to the grave structural defects which exist. One of these—the absence of an infirmary—will in all probability be soon remedied, as the plans for such a building have been completed and are only awaiting the sanction of the Local Government Board. But unfortunately the receiving wards are totally unfitted for their purpose, and it is quite obvious that so long as the provision for dealing with cases on their very entry is inadequate all the care that may be taken in other departments of the building will be rendered futile. With regard to administrative questions it is quite apparent that the nursing staff, if it is to be properly effective, must be thoroughly reorganised. Appended to the report is a gratifying testimonial to the staff of the institution, to whose loyal and persevering efforts the Medical Officer attributes much of the progress that has been made during the year.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Cases. Dr. Sansom: Addison's Disease treated by Supra-renal Extract.—Mr. Harold: Congenital Feeble-mindedness associated with Congenital Deficiency of the Chest-wall and with Cardiac Disease.—Mr. Wallis: (1) Wired Patella for Fracture in a Man aged seventy; (2) Compound Comminuted Fracture of the Skull, with Facial Paralysis.—Dr. L. Guthrie: (1) Spina Bifida Occulta with Paresis of Leg; (2) Postero-lateral Sclerosis.—Mr. S. Edwards: Case after Nephrectomy for Injury (with specimen).—Dr. Savill: Cases of Telangiectasis.—Mr. S. Boyd: Temporary Resection of Upper Jaw for Naso-pharyngeal Growth.

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Dr. Frederic Hewitt and Mr. A. M. Sheild: On Posture in its Relation to Surgical Operations under Anæsthetics (adjourned discussion).—Dr. R. A. Gibbons: Renal Colic in Infants.

WEDNESDAY.—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-sq., W.).—5 P.M. Cases, Specimens, &c., by Dr. J. B. Ball, Dr. F. W. Bennett, Mr. A. A. Bowlby, Dr. A. Bronner, Mr. H. T. Butlin, Dr. Wm. Hill, Dr. A. A. Kanthack, Dr. Percy Kidd, Dr. Edward Law, Dr. Scanes Spicer, and Mr. W. R. H. Stewart.

HUNTERIAN SOCIETY.—8 P.M. Clinical Evening. Mr. W. Campbell McDonnell: Case of Congenital Ataxia.—Mr. Targett: Excision of Temporo-maxillary Joint in a Child.—Dr. Sequeira: Nystagmus.—Dr. Glover Lyon: Imperfectly developed Pinna.—Dr. Fred. J. Smith: Paroxysmal Hæmeglobinuria with Local Asphyxia.—Sir Hugh Beevor: Cases of Cervical Herpes, and of Retracted Lung in a Boy of four.—Dr. Ettles: Cases of Distension of Left Frontal Sinus, and of Horizontal Nystagmus.

SOUTH-WEST LONDON MEDICAL SOCIETY (Stanley's, 235, Lavender-hill).—8 P.M. Dr. Chas. W. Chapman: Heart Disease in the Young, its Management and Treatment.

THURSDAY.—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-st., Cavendish-sq., W.)—8 P.M. Card Specimens:—Mr. Wray: Case of Detachment of the Retina after Treatment.—Mr. Stephenson; Irideremia in Two Brothers.—Dr. Bronner: Tumour of Lacrymal Gland.—Mr. Hartridge: Retinitis Circinata.—Mr. Tweedy: Multiple Foreign Bodies in an Eye retaining Normal Vision.—Mr. Work Dodd: Case of (?) Congenitally Small Field of Vision. 8.30 P.M. Papers:—Mr. W. H. Jessop: Some cases of Graves' Disease with Destruction of Eyes.—Mr. C. Wray: The Treatment of Detachment of the Retina.—Messrs. Eales and Sinclair: Uveal Cyst of the Iris.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens by Dr. Elder (Nottingham) and Mr. Skene Keith. Papers:—Dr. Elder (Nottingham): (1) The Present Condition of a Patient operated upon in April, 1894, for Double Ovarian Papillomata; (2) Notes on a Porro's Operation.—Mr. Skene Keith: Unusual Complications in two cases of Removal of the ovaries.—Dr. Halliday Croom: Glycosuria complicating an Ovarian Tumour and Ovariotomy.—Dr. John Shaw: Short Note on a Complication impeding the Convalescence of a case of Oöphorectomy.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Great Northern Central Hospital, Holloway-road, N.).—8.30 P.M. Clinical Evening. Cases will be shown by Mr. Brooke, Mr. Hamilton, Mr. Mower White, Mr. T. P. B. Beale, Dr. R. C. Beale, and Dr. James Galloway.

FRIDAY.—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-sq.).—8 P.M. Mr. T. W. Thompson: Considerations in respect to "Return" Cases of Scarlatina.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, W.).—8.30 P.M. Adjourned Discussion on "Gastric Ulcer" to be opened by Mr. C. B. Keetley. Dr. Drewitt, Dr. Clippingdale, Mr. S. Edwards, Mr. Wharry, Mr. Bidwell, and Mr. Eccles will take part.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. Whistler: Tuberculosis of the Larynx.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Impulsive, Homicidal, and Moral Insanity.

ROYAL COLLEGE OF PHYSICIANS, LONDON.—5 P.M. Dr. J. B. Bradbury: On Some New Vaso-dilators. (Bradshaw Lecture.)

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

HOSPITAL FOR CONSUMPTION &c. (Brompton).—Dr. R. Maguire: Aortic Disease.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—5 P.M. Dr. Morgan Dockrell: Diseases of the Hair.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Turner: Neurological Cases.

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Mr. John H. Morgan: Surgical Cases.—National Hospital for the Paralysed, Bloomsbury, 2 P.M., Dr. Taylor: Syphilitic Disease of the Nervous System.—Central London Sick Asylum, Cleveland-st., 5.30 P.M., Dr. W. Hale White: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M. Prof. Crookshank: Typhoid Fever and Diphtheria.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Craig: General Paralysis of the Insane.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Parasitic Diseases (Vegetable).

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

JEAN JACQUES ROUSSEAU ON TIGHT-LACING.

To the Editors of THE LANCET.

SIRS,—There are probably few sumptuary topics about which more has been written than the feminine habit of seeking to improve upon nature by mechanical means, but I greatly fear that for all the good their admonitions have brought forth the well-meaning scribes might just as well have saved their labour. Fashion is a power against which it is vain to cope, and so long as that mysterious authority chooses to decree small waists, small waists we shall see though livers grow furrowed and kidneys break loose from their anchorages. At one of the numerous congresses that were held in Bordeaux the Hygiene of Clothing was the object of a discussion which was initiated by Dr. Solovief, but, inasmuch as all the discussers belonged to the ruder sex, it will readily be conceived that the proceedings savoured of monotony. It goes without saying that the manifold atrocities of the corset came up for universal reprobation, but although the denunciators of that unspeakable garment were full of eloquence it is no disparagement of their powers to say that not one of them was equal to Rousseau. Here is what the philosopher of Vevay wrote in "Sophie, ou la Femme" more than a hundred years ago.

"We know that the easy-fitting clothing of the ancients, which nowhere incommoded the body, contributed largely towards the preservation in both sexes of those exquisite proportions that we still may see in statues—proportions which nowadays have to serve as models for artists because disfigured nature has ceased to supply any. Of all those Gothic shackles, those multitudinous ligatures which impede our limbs in every direction, they did not have a single one. Their

Digitized by Google

women knew naught of those whalebone contrivances by means of which ours cripple the forms which they vainly imagine they are improving. I am quite incapable of imagining that this abuse, which in England they push to an inconceivable point, could possibly end otherwise than by causing degeneration of the species; and I even go so far as to maintain that the fascinating result aimed at is in bad taste. It is not an agreeable spectacle to see a woman cut in two like a wasp; it shocks the eye and wounds the imagination. Slenderness of the waist, like everything else, has its proportions, its proper measurements, and to depart from these is most certainly a defect. In the nude the eye could not fail to appreciate the incongruity of a too-slender waist; how, then, can it be reckoned a beauty beneath clothing? I do not dare to dwell upon the motives which induce women to insist on, as it were, encasing themselves in armour — a drooping bosom, an enlarging abdomen, &c. I admit that these things are not pleasing in a young person of twenty, but at thirty they are no longer shocking; and inasmuch as we are compelled, whether we like it or not, to remain at all times exactly as nature pleases—and seeing, moreover, that in these matters a man's eye is not to be hoodwinked—it is evident that these defects are less displeasing at any age than the silly affectation of posing for a young girl at forty. *Everything that impedes or constrains nature is in bad taste;* this is just as true of garments for the body as it is of ornaments for the mind. Life, health, reason, comfort, should weigh more than aught else; *grace cannot be present where ease is absent*, delicacy is not languor, and one need not be unwholesome to give pleasure. Pity is excited by suffering, but pleasure and desire seek for freshness and health."

I am, Sirs, yours faithfully,

Nov. 4th, 1895. A FAMILY MAN.

*** We have at different times spoken our minds concerning tight-lacing and the mis-shapen corset. But the well-fitting corset is a valuable article of attire. With different modifications it becomes, as all in our profession know, a useful surgical instrument; and the ordinary corset provides a grateful support in many conditions.—ED. L.

Mr. A. C. Elmore's letter was acknowledged in our issue of Oct. 19th, p. 1020. We must have full names and dates in support of his statements before we can consider the advisability of publishing his letter.

X.—We cannot answer general questions on such topics, as every separate case has a right and a wrong. If our correspondent will state the particular case we will advise him.

Mr. J. B. Pike.—We do not think the moment opportune to publish quite so contentious a letter.

Dr. A. Butler Harris is thanked for his communication.

TUBERCULOSIS AND SCROFULA.

To the Editors of THE LANCET.

SIRS,—In your report of Mr. Treves's address at Manchester he is made to say: "The tuberculous individual is the one whose tissues form a suitable soil for the development of the bacillus." A little earlier he defines tuberculosis "as an infective disease in which the tissue changes are due to ..... the tubercle bacillus." These statements I find much difficulty in reconciling, and cannot see how an individual can be "tuberculous" into whom no tubercle bacillus has entered, according to the latter of the two statements quoted. For this pre-tuberculous condition, which is quite defined, I think the term scrofula (or possibly struma as less abused) a reasonable one until more is known of this stage or condition. Many individuals may undoubtedly be termed scrofulous who just as certainly could not be termed tuberculous. As a lesion of this character the swelling of the upper lip and nose, so common in scrofulous children, may be mentioned. Doubtless not a few enlargements of the lymph glands are also of a similar character. The scrofulous condition is one of hereditary malnutrition and vulnerability to various injuries, of which the tubercle bacillus is no doubt the most important, though many others exist, as cold and overstrain. Tuberculosis is damage done to the tissues by the tubercle bacillus. Scrofula may be an unsatisfactory term, and has been wrongly applied to many tuberculous lesions; it, nevertheless, describes sufficiently a definite condition about which we know little, and yet one that ought not to be condemned as tuberculosis. The abuse of the term is not yet sufficient argument against its use.

I am, Sirs, yours truly,

Nov. 5th, 1895. RICHMOND LEIGH.

THE HEALTH OF EURASIANS.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers could tell me where I can find information regarding the health and physique of Eurasians and of their offspring. I am, Sirs, yours truly,

Nov. 5th, 1895. ETHNOLOGIST.

M.B.—The information will be found in THE LANCET of March 21st, 1891. But we believe that the patentee is dead, and we do not know where the article is obtainable.

M.D.—"The Woman who Wouldn't" (Simpkin, Marshall, Hamilton, Kent, and Co.); "Baby Buds" (Mrs. Wostenholme Elmy, Buxton House, Congleton), 1*s.*

Mr. John Bickerdyke is thanked for his communication.

MEDICAL ADVERTISING AT TENTERDEN.

A handbill has been sent to us, said to have been left in every shop in the town, announcing a Course of Lectures to Ladies by "Dr. Redman, Surgeon Lecturer *(sic)* and Hon. Life Member St. John Ambulance Association." All ladies interested are invited to attend. The charge is 2*s.* 6*d.*, and each lecture is to be illustrated by a practical demonstration. Our opinion is asked of this proceeding. We cannot approve of it and we trust that Dr. Redman will reconsider it in the light of professional objections to all sorts and methods of advertising the names of medical men.

MEDICAL MEN who may possess the current issue of the "Komical Kalendar," edited by Howard Paul, will have been astonished at the contents of the page allotted to the 301st day of this year, which are as below:—

301 **1895.** 64

OCTOBER

28

MONDAY

Doctor X. is not a crack shot, and is not remarkable as a physician; but despite this fact, when the shooting season comes round, he spends a fortnight in the fields with dog and gun.

"And that's the only period of the year when he doesn't kill anything," remarked Dr. Robson Roose, with a twinkle in his other eye.

Dr. Roose is doubtless ignorant of the way in which his name is being used. We trust that Mr. Howard Paul will in future years display better taste and not use the name of a living medical practitioner to give point to an offensive "chestnut."

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—In view of the frequent remarks in THE LANCET and at the last meeting of the British Medical Association concerning medical advertising, I bring under your notice the enclosed cutting, which I took out of a recent copy of the *Irish Times*. From it you will notice that the honorary secretary of a general hospital gives his name, qualifications, and private address at the bottom of the advertisement of this hospital, a thing which to my mind is wholly unnecessary and can have but one object. The advertisement, as it is on the enclosed cutting, appears daily in the *Irish Times*. Trusting you will give the matter your attention and thanking you in anticipation,

I am, Sirs, yours truly,

Nov. 4th, 1895. A CONSTANT READER.

*** We think that it would be highly advisable that the honorary secretary in question should take steps to have his official correspondence directed to the hospital, making arrangements to have it forwarded thence to his private address, if it is more convenient to him to transact the hospital business at home. With regard to our correspondent's other queries: (*a*) Licentiates are not entitled to the style of "Dr."; (*b*) the assistant's work should certainly be done under the principal's active supervision, and the principal is the only person who would be officially recognised.—ED. L.

Parish Council.—B. has the claim of propinquity, but the Parish and the Local Government Board have the gift of the appointment.

R. W. S.—We do not recommend individual practitioners or give medical advice.

"WHAT IS LIFE?"

To the Editors of THE LANCET.

SIRS,—Without plunging into any metaphysical speculations, may I be allowed to ask whether the question propounded by scientists—"What is life?" is altogether a rational one? It would appear that investigations as to what conditions may produce, bring about, or manifest life are held as synonymous with life itself. For example, let us suppose chemists, by some synthetical process apart from any living matter, could so operate on inorganic matter as to produce or change this inorganic matter into living matter. It is clear we should have in such case no facilities by which we could recognise life as an entity other than we now possess. It is true we should manifest life for ourselves in lieu of life being manifested for us through nature; but we should have no comprehension of life *as an entity* beyond our present comprehension—hence, I submit, we should be no nearer in answering the question, "What is life?" than we now are.

I am, Sirs, yours truly,

Queen's-road, S.E., Oct. 29th, 1895. CLEMENT H. SKES.

During the week marked copies of the following newspapers have been received:—*Newcastle Daily Leader, Sussex Daily News, Brisbane Courier, Western Daily News, Maidstone Journal, Northern Echo, Sheffield Independent, Andover Advertiser, Devon Standard, Newcastle Chronicle, Goole Times, Citizen, Walsall Advertiser, Brighton Gazette, Boston Herald, Meat Trade' Journal, Carrickfergus Advertiser, Keble's Margate and Ramsgate Gazette, Clacton Gazette, Cheltenham Examiner, Cornish Times, Newark Herald, Licensed Victuallers' Gazette, Alliance News, Cornwall Gazette, Bath Herald, Electrical Review, Toronto Mail, Western Mail, Birkenhead News, Guernsey Star, Egyptian Gazette, Malton Gazette, &c., &c.*

Pharmaceutical Products of High Repute.

SACCHARIN "TABLOIDS."

In cases of Diabetes Mellitus, Glycosuria, Gout, Obesity, and all diseases in which sugar is contra-indicated, dietetic regimen is almost always looked upon as more or less of a penance, and patients are sure to be thankful if their food can be made more palatable and varied by means of a harmless condiment.

Diabetic patients, from the very fact that sugar is denied to them, often have such a craving for sweet things that the withholding of them exercises great influence on their mental condition. This shows the enormous benefit which the introduction of saccharin in a soluble form has conferred upon all those whose bodily conditions make it necessary that sugar in every form should be avoided. It is not too much to say that monotonous and unpalatable diets do more harm to many patients than the diseases from which they suffer.

The absolute harmlessness of Saccharin has been conclusively proved by numerous and thorough scientific experiments and researches, and experience has corroborated the results arrived at. It has been shown that Saccharin produces no injurious effects whatever upon the body; that it is discharged, unchanged and in its entirety, through the urine and fæces; that it is absolutely inoperative as a retarding agent on bodily functions; for instance, it exercises no influence on either assimilation or digestion. When, therefore, sugar (the ordinary carbohydrate) in any form is prohibited as an article of food or as a condiment, it may be asserted, without fear of contradiction, that Saccharin, while satisfying the palate of the patient, cannot possibly aggravate the existing malady; on the contrary, its antiseptic influence may be for good.

Saccharin is invaluable as a sweetening agent for unpalatable medicines where sugar is contra-indicated, or where it is desired to make the volume of medicine as small as possible. In the form of soluble Saccharin powder it is sent out in little oval bottles with a tiny spoon attached to the stopper, each spoonful holding an equivalent in sweetening potency to one lump of loaf sugar. The many varieties of gluten food, such as gluten bread, biscuits, &c., may be conveniently and pleasantly flavoured by means of this preparation. Perhaps a more palatable and convenient form of Saccharin is the "Tabloid" prepared by compressing this chemical. "Tabloids" are of the greatest convenience to those travelling or away from home during the day, as each tiny "Tabloid" is equivalent to a lump of sugar and may be substituted for that flavouring agent for sweetening tea, coffee, &c.

Soluble Saccharin Powder is supplied to the medical profession in ¼-oz. and 1-oz. bottles with scoop, at 1/2 and 3/10 per bottle. Saccharin "Tabloids," containing ½ grain in each, are supplied in bottles of 100 and 200 at -/7 and 1/1 each.

MENTHOL SNUFF (B., W. & CO.).

This preparation has become deservedly celebrated for its marked local anæsthetic, vascular, stimulant, and antiseptic properties. It has been approved by the highest medical authorities for its sedative action on the nerve terminations, and for its property of causing prompt contraction of the relaxed nasal vessels. It is composed of menthol, cocaine, (⅛th per cent.) ammonium chloride, camphor, and lycopodium. It has been suggested to us that the issue of a smaller size would increase the sphere of its usefulness, and we have accordingly decided to issue a small size in addition to our older 1/- size.

Supplied to the Medical Profession in attractive tin boxes at -/5 and -/8 per box.

TEREBENE.

Terebene has been found of the most decided utility in the treatment of many bronchial troubles. The drug tends to liquefy the sputum and facilitate expectoration; these qualities are enhanced by its inherent antiseptic properties when employed as an inhalant in the treatment of chronic pulmonary affections, as it exerts its antiseptic influence at the seat of infection. Terebene is more generally employed as an inhalant. If the vapour is to be inhaled dry, the Terebene may be used with a B., W. & Co. "Pinol-Eucalyptia" Dry Inhaler or a Menthol Pocket Inhaler.

Terebene supplied to the Medical Profession, in 1-oz., 2-oz., 8-oz., and 16-oz. bottles, at -/9, 1/-, 2/-, and 3/9 each.

"EMOL-KELEET."

Since our earlier notices to the medical profession regarding this preparation we have received many encouraging reports of the beneficial effects of its use in Surgery and Dermatology. It has not only been prescribed for its absorbent, antipruritic, and emollient qualities, but also as a diluent for such antiseptic agents as Loretin, Dermatol, Iodoform, Boric Acid, Chrysophanic Acid, Hydro-Naphthol, &c. Owing to the fact that it is a natural powder containing a large proportion of native silicates, "Emol-Keleet" is chemically stable, and is therefore freely prescribed as a diluent for potent medicinal agents without fear of combination taking place. In addition to these chemical advantages, its soft, silky texture, soothing influence, and other physical qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other drying and dusting powders have failed.

THE LANCET, in an appreciative notice of this preparation, says: "On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

BRAITHWAITE'S RETROSPECT OF MEDICINE eulogises it as: "The most beautiful, impalpable mineral powder with which we are acquainted ..... it promises to supersede all the older forms of dusting powder."

Price to the Medical Profession, -/9 per box.

A DELICIOUS FAT FOOD.

Maltine WITH COD LIVER OIL

COD LIVER OIL FREE FROM DISAGREEABLE FEATURES.

Contains a satisfactory proportion of the best Cod Liver Oil, rendered easy of assimilation, and acceptable to the palate by means of perfect incorporation with a palatable, digestive Food-"Maltine." The question of a "substitute for Cod Liver Oil" (which has not as yet been satisfactorily settled) need not disturb the Physician who prescribes "Maltine with Cod Liver Oil": it is not only the most palatable and digestible Fat-food, but it contains the specific properties of Cod Liver Oil, deprived of all disagreeable features, though unaltered as regards chemical constitution. This last is a most important point and serves to differentiate "Maltine" with Cod Liver Oil unmistakably from the various "Emulsions of Cod Liver Oil." As is well known, the method of procedure in their case is to saponify the oil with an alkali.

"Maltine" with Cod Liver Oil compared with Emulsions.

The result of this chemical treatment is to completely change the characteristics of the oil, and probably to destroy some of its most important factors. These emulsions are also broken up by the addition of acid, and consequently, when acted upon by the gastric juice, the Oil is liberated, giving rise to all the inconveniences that follow the ingestion of the plain Oil.

Advantages of "Maltine" with Cod Liver Oil.

The union of the Oil with the Maltine is effected by a special *mechanical* process.

The combination is stable, being unaffected by acid or alkaline reagents.

The chemical constitution of the oil is unaltered.

It is the most palatable preparation of Cod Liver Oil, never occasions nausea, but on the contrary is readily tolerated, and appears to be thoroughly assimilated.

These advantages have secured for "Maltine" with Cod Liver Oil the general support of Medical Men, who can from their own observation, confirm the dictum of the BRITISH MEDICAL JOURNAL:—

"Patients unable to tolerate the purest and most carefully prepared Cod Liver Oil can readily digest and assimilate it when combined with 'Maltine.'"

In prescribing, please specify "MALTINE CO."

SAMPLES FREE TO MEDICAL MEN.

The Bradshaw Lecture

ON

SOME NEW VASO-DILATORS.

Delivered before the Royal College of Physicians of London on Nov. 12th, 1895,

BY J. B. BRADBURY, M.D. CANTAB., F.R.C.P. LOND.,

DOWNING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE; PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

MR. PRESIDENT,—My first duty, Sir, is to thank you, as I do most sincerely, for the great compliment you have paid me in asking me to deliver the Bradshaw Lecture of 1895. To most of those present it is known that this lectureship was founded by the widow of William Wood Bradshaw, of Andover and Reading, who was a member of this College and a Master of Arts and Doctor of Civil Law of the University of Oxford. In thus wishing to perpetuate the memory of her husband Mrs. Bradshaw stipulated that the subject of the lecture should be "connected" with some question of medicine or surgery. Having recently undertaken in my capacity as Downing Professor of Medicine in the University of Cambridge to teach and advance to the best of my ability the subjects of pharmacology and therapeutics, it occurred to me that I could not do better on the present occasion than address you on a subject in this department of medicine—and here I wish to express my obligation to my assistant, Mr. Marshall, who has rendered me invaluable aid in conducting the experiments mentioned in the lecture. I propose, then, to ask your attention to certain vessel dilators, which, so far as I am aware, have not previously been brought before the notice of the profession.

The vaso-dilating action of nitrites and nitro-glycerine has long been known, and the whole subject of their action was ably reviewed and further extended by Professor Leech in the Croonian Lectures of 1893. But, as you are aware, these compounds possess a powerful though more or less transient action, and, as in some conditions, it would be advantageous to possess a drug having a more prolonged though less powerful effect, it has been the endeavour of pharmacologists to discover such a substance. With this end in view Professor Matthew Hay[1] experimented with ethyl nitrate, nitro-cellulose, and allied bodies, but came to the conclusion that these were of no practical value. Later, Dr. Leech, investigating the action of the nitrates of the fatty series, found that all these bodies possessed a dilating effect, which is generally of a prolonged kind.[2] He suggested them as remedial agents, but at the same time pointed out their liability to cause headaches. Still more recently Dr. Lauder Brunton has experimented with hydroxylamine hydrochlorate, but he found this compound liable to cause gastric disturbance.[3]

As all the alcoholic nitrates previously examined had been found to be vaso-dilators, and as the only multivalent nitrate used, viz., nitro-glycerine, has a powerful influence in this direction, it seemed not improbable that the drug in quest might be found among the nitrate derivatives of the higher-valent alcohols or their allies. The nitrates of erythrol, mannitol, and some of the sugars were therefore examined; later the series was extended; but it is mainly to the results of the examination of the bodies just mentioned and their possible bearing on therapeutics that I ask your consideration. Chemically, as you are probably aware, nitrates consist of an NO_2 group united to a radicle by a bond of O, thus $R.O.NO_2$. True nitro-bodies on the other hand consist of an NO_2 group united to a radicle by the N atom directly—i.e., without the intervention of an O atom—e.g., $R.NO_2$. Although I may occasionally use the expression nitro-compounds, all the bodies we are dealing with are in reality true nitrates. Unfortunately the term "nitro" in reference to these bodies has become so familiar from long use that it is difficult to discard it altogether.

Preparation.—All the substances I have experimented, with were obtained by nitrating the alcohols or corresponding compounds by means of a mixture of nitric and sulphuric acids at a low temperature. The product obtained was well washed with water and dilute alkaline solution until free from acid and was subsequently dried. The solid nitrates were afterwards crystallised from ethylic alcohol or ether. From the alcohols the following series was prepared:—

Methyl nitrate	$CH_3.ONO_2$	B.P. 65° C.
Glycol (ethylene) di-nitrate	$CH_2.ONO_2$ | $CH_2.ONO_2$	—
Glycerol tri-nitrate (nitro-glycerine)	$CH_2.ONO_2$ | $CH.ONO_2$ | $CH_2.ONO_2$	M.P. -20° C.
Erythrol tetra-nitrate	$CH_2.ONO_2$ | $(CH.ONO_2)_2$ | $CH_2.ONO_2$	M.P. 61° C.
(Arabinol penta-nitrate)	—	—
Mannitol hexa-nitrate	$CH_2.ONO_2$ | $(CH.ONO_2)_4$ | $CH_2.ONO_2$	M.P. 113° C.

Arabinol penta-nitrate, which would occupy the place intermediate between the erythrol and mannitol compounds, has not yet been prepared. Among the sugars the nitrates of dextrose, levulose, and saccharose have been investigated. Constitutionally these bodies differ from the alcoholic nitrates in containing an aldehyde or ketone group and fewer nitrate (NO_3) groupings. Other nitrates, those of cellulose and starch, have also been examined, but as these have no bearing on therapeutics I shall not deal with them further. The composition of the nitrates used was determined by means of a Lunge's nitrometer. This gives off all the nitrogen in these compounds as nitric oxide (NO) from which the number of NO_3 groups in the body can be determined.

Properties.—Of the nitrated alcohols the first three are liquid at the ordinary temperature of the air, the others are solid and crystalline. When pure they are colourless, and if kept in a dark and moderately cool place are stable. Exposed to sunlight or warmth they gradually decompose, turning yellow and giving off nitrous fumes. Heated rapidly or subjected to percussion they explode. Methyl nitrate distils at 65° C.; but the boiling points of the glycol and glycerol-nitrates have not been determined as these bodies rapidly decompose as their boiling points are approached. Erythrol nitrate melts at 61° C. and the mannitol compound, according to Socoloff, at 113° C. All these nitrates are more or less soluble in water, their solubilities showing a gradual transition from the methyl (the most soluble) to the mannitol (the least soluble) compound. In all cases the solubility in water is slight, but in alcohol and ether they are readily soluble. The nitrated sugars, as I have obtained them, are white or slightly yellow tenacious masses, decomposing readily, and difficult to prepare in the pure state. Like the corresponding alcoholic esters they are readily soluble in alcohol and ether, and slightly so in water. All the nitrates when heated with alkalies give the nitrite reaction—i.e., they liberate iodine from a slightly acidified solution of potassium iodide, and produce certain colour reactions (the meta-phenylene-diamine test, &c.).

PHARMACOLOGICAL ACTION.

All the soluble organic nitrates of the composition $R.ONO_2$ hitherto examined dilate blood-vessels and change the normal spectrum of the blood. Their activity however varies within wide limits, and appears to be due to their different solubilities and liability to decomposition. The latter is, perhaps, the more potent factor,[4] as methyl nitrate—the most soluble compound—has a comparatively slight vaso-dilating effect. On the other hand, glycol di-nitrate, the least stable, has a powerful action, closely resembling that of nitro-glycerine. Its effect, however, is more transient. The erythrol and mannitol nitrates and the nitro-sugars, being less soluble than the other compounds, have a correspondingly weaker effect, but, as we shall see, their action is more prolonged.

The vaso-dilating action of these bodies has been determined by means of perfusion experiments on both warm- and cold-blooded animals, and the duration of

[1] The Practitioner, vol. xxx., p. 321.

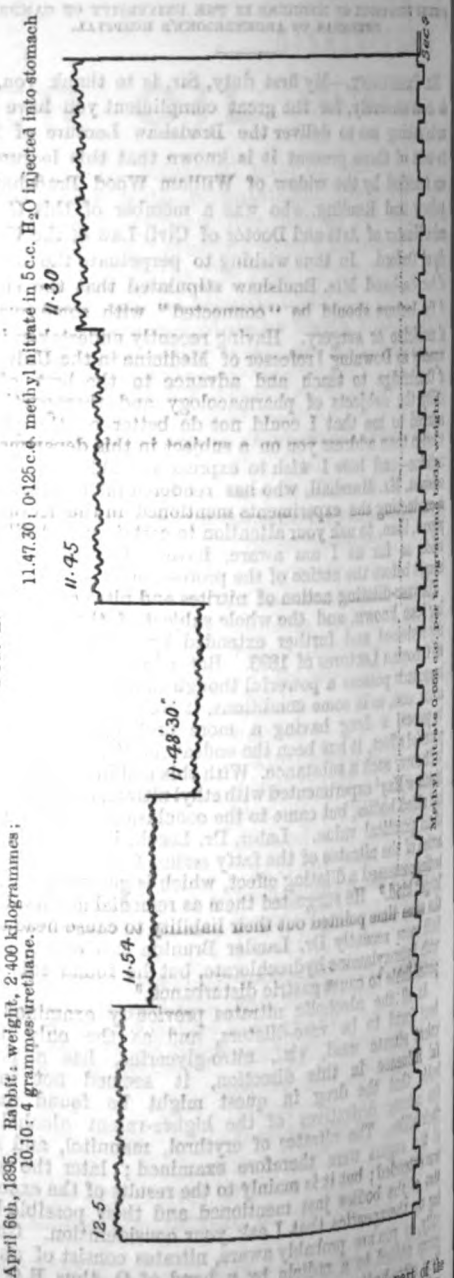
Digitized by Google

this action by their effect upon the blood pressure in animals and the pulse in man. Nitro-glycerine has been largely experimented with, but as the vessel-dilating effect of this drug is now so well known I shall say little further about it. For the purposes of this lecture the diagrams of nitro-glycerine may be looked upon as standards of action with which the activity of the other drugs can be compared.

Perfusion experiments.—The method of perfusion through excised organs, which we owe to the genius of Ludwig, demonstrates absolutely the direct effect of drugs upon blood-vessels. In such experiments there is no question of nervous action, except it be a purely local one. But whether the effect of an agent be upon the terminal nerve fibrillæ and intra-mural nervous ganglia or upon the muscular tissue of the vessel walls is of little moment. For all practical purposes it is sufficient to know that a drug acts either directly or indirectly—i.e., chiefly upon the peripheral vessels or upon the vaso-motor centre. For determining the action of these agents upon the vessels of warm-blooded animals the kidney of the sheep, as being most readily procurable, was used. For the effect on cold-blooded animals frogs and water-tortoises were employed. But in all the general effects obtained were the same, and I shall therefore confine myself to my experiments on the former. In all the experiments except those with methyl nitrate a presumable strength of 1 of the drug in 10,000 of blood was used (I say "presumable" because in a few instances, notably those of the nitrates of mannitol and the sugars, complete solution of the drug may not have occurred). By means of ovens the excised organ and blood were kept at the normal temperature (37° to 38° C.), and the blood was perfused under a constant pressure (70 mm. of mercury). The outflow of blood from the vein was measured at intervals of a minute, first during the passage of normal blood, and subsequently during the flow of

FIG. 1.

March 23th, 1895. Rabbit, weight, 1·900 kilogrammes; 10.45: 3 grammes urethane.



Urethane 1·5 grammes per kilogramme body weight.

nitrated blood. Methyl nitrate in the strength of 1 in 10,000 has scarcely any dilating effect. In 1 in 1000, however, it transformed a normal venous flow of 23 c.c. per minute to one of 33 c.c. per minute. After the perfusion of normal blood the venous outflow again reached its former level. A second and a third time vascular dilatation was produced by the nitrated blood and each time was followed by contraction when the normal blood was perfused. The other nitrates are much more powerful. Di-nitrate of glycol perfused in the strength of 1 in 10,000 increased the outflow from 9 c.c. per minute to 23 c.c. per minute, and nitro-glycerine in the same strength converted a normal outflow of 9 c.c. to one of 19 c.c. per minute. In both cases contraction immediately followed the perfusion of normal blood, and a second and a third time marked dilatation was produced by the perfusion of nitrated blood. Erythrol and mannitol nitrates also caused marked dilatation, the former increasing the venous outflow from 13 c.c. to 35 c.c. per minute, the latter from 6 c.c. to 11 c.c. per minute. A nitrate of dextrose containing four NO_3 groupings, and therefore corresponding to a tetra-nitrate, when perfused increased a normal outflow of 14 c.c. to one of 26 c.c. per minute; similar results have been obtained with the other nitrated sugars. There can, therefore, be no doubt as to the capability of these bodies to dilate bloodvessels; but, as I have previously intimated, what we want to know for therapeutic purposes is the duration of their action. This is shown in the blood pressure and pulse tracings.

Blood-pressure tracings.[5]—The blood-pressure tracings were mostly taken from rabbits which were kept under the influence of urethane, a drug exerting scarcely any effect upon the blood pressure (Fig. 1). In the case of the glycol and glycerol nitrates an amount of drug corresponding to 0·025 gramme per kilogramme of the body weight was introduced. In this dose methyl nitrate had scarcely any effect, and therefore a dose of four times this amount—i.e., 0·052 c.c. per kilogramme body weight—was used. Even in this dose, as we shall presently see, the effect was slight and transient. With the solid bodies doses of 0·025 gramme and 0·05 gramme

FIG. 2.

per kilogramme body weight were used, but as part of the substance could be extracted from the contents of the stomach after the completion of the experiment this does not represent the amount absorbed. In the case of the liquid bodies the substance was dissolved, and in the case of the solid bodies in part dissolved and in part suspended in weak ethylic alcohol, the mixture being injected through a catheter into the stomach. The effect in the several cases is

[5] I take this opportunity of thanking Professor Schmiedeberg of Strassburg for allowing my assistant the use of his laboratory for this purpose.

...own in the diagrams. Both glycol di-nitrate and glycerol ...i-nitrate (nitro-glycerine) have a powerful action. The ...rmer (Fig. 3) in one minute reduced the blood pressure ...om 112 mm. of mercury to 85 mm., and in four minutes to ...2 mm. The pressure then gradually rose, and fourteen ...inutes after the administration stood at 106 mm. of ...ercury. Later the blood pressure again fell, probably ...wing to further absorption of the drug, and later still com- ...enced to rise again. Under similar circumstances nitro-

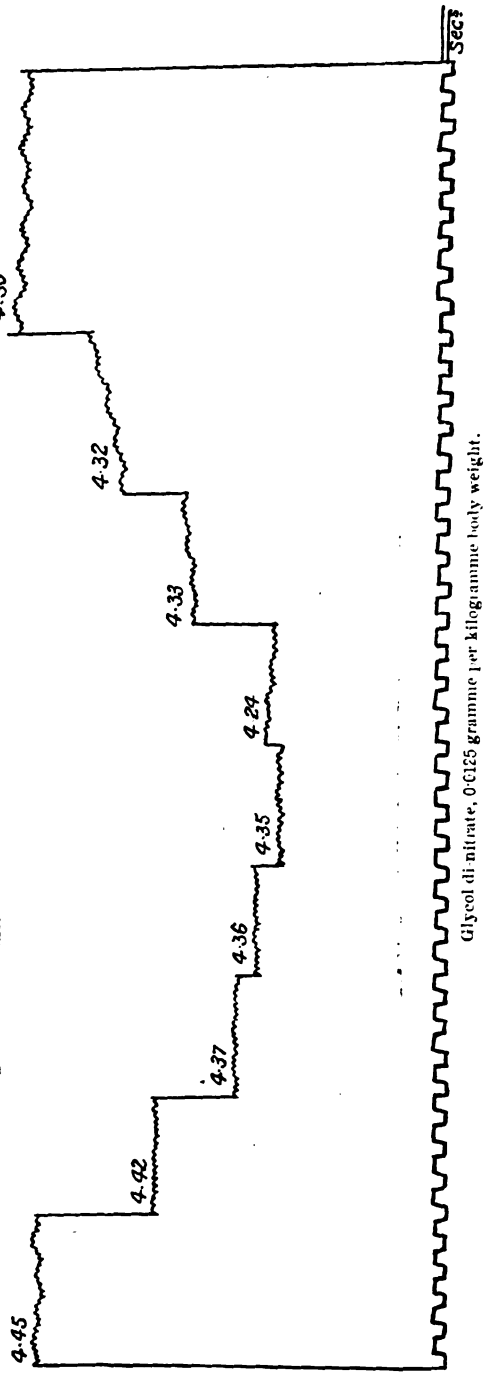

FIG. 3.

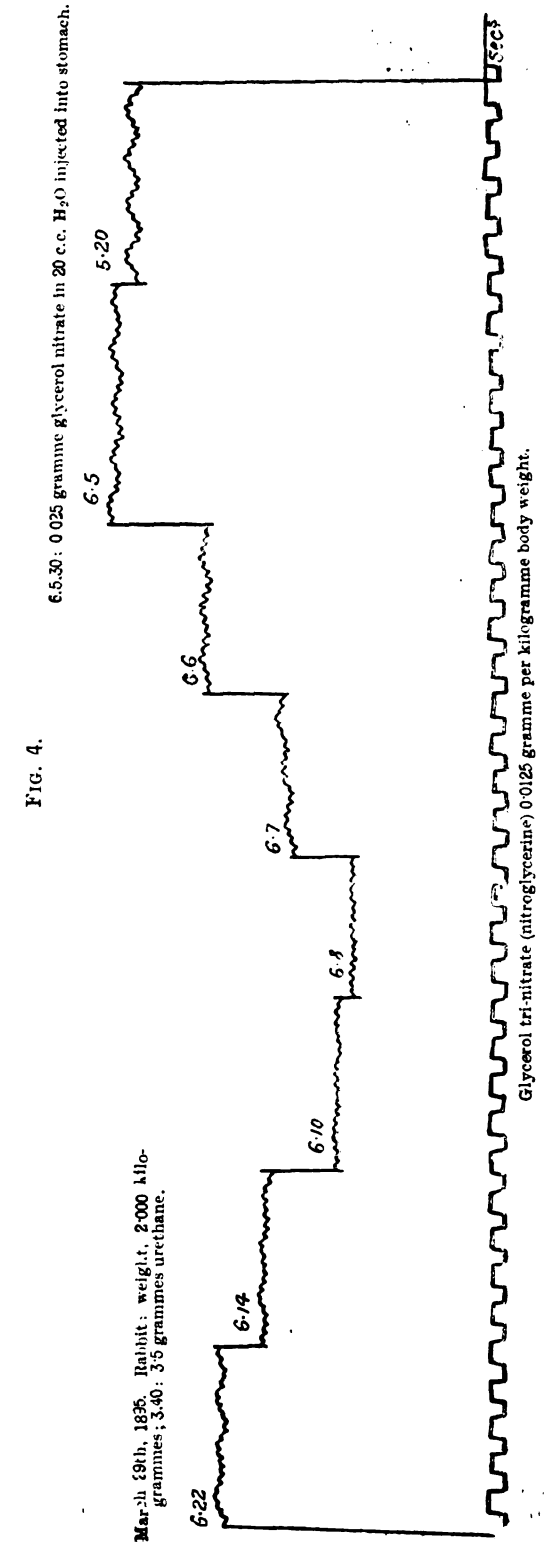
glycerine produced an almost identical effect (Fig. 4). In one minute the pressure was reduced from 100 mm. of mercury to 76 mm., and in three minutes and a half to 37 mm. It then commenced to rise, and seventeen minutes after the administration of the drug stood at 71 mm. The effect of erythrol and mannitol nitrates is much less evident. No abrupt fall of pressure occurs, but there is also no subsequent return to normal. Twenty-eight minutes after the introduction of erythrol nitrate (Fig. 5) a fall of pressure from 85 mm. of mercury to 63 mm. occurred, and thirty minutes later the fall was further increased to 54 mm. The subsequent fall was trifling; two hours and forty-eight minutes



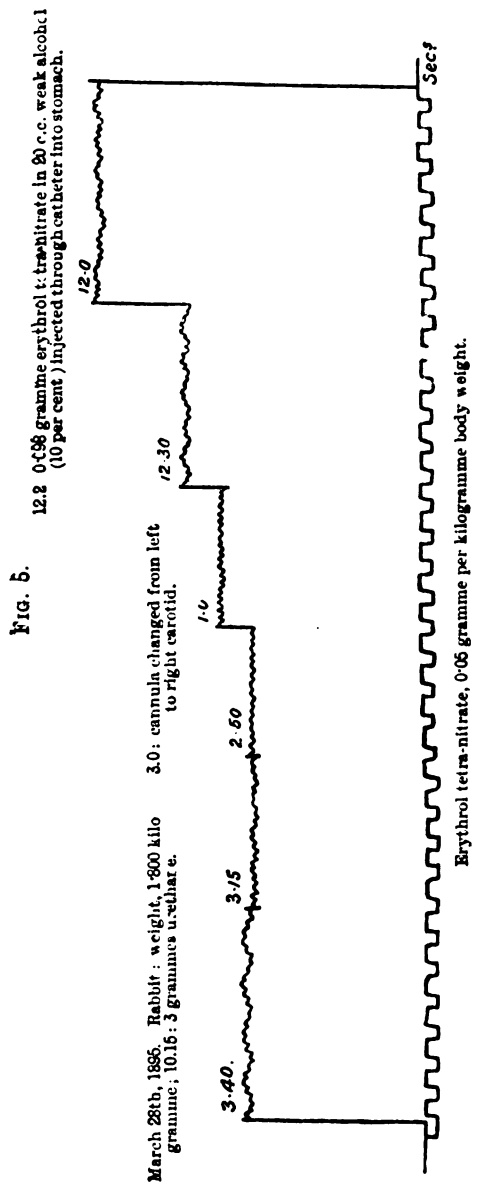


FIG. 4.

after the administration of the drug the pressure was 46 mm. of mercury, and an hour later it stood at the same level. In the meantime the cannula had been changed from the left to the right carotid owing to a clot having formed in the

Digitized by Google

former vessel. After mannitol nitrate a similar effect occurred (Fig. 6). Twelve minutes after the introduction of the drug the blood pressure had fallen from 98 mm. of mercury to 84 mm.; an hour later it had fallen to 60 mm. Subsequently a slight rise, followed by a fall, occurred; four hours and twelve minutes after the commencement of the experiment the blood pressure still remained at 58 mm. of mercury. The effect of methyl nitrate upon the blood pressure is slight. After introducing 0·125 c.c. of the substance (i.e., about four times the quantity used in the case of the other liquid nitrates), dissolved in 5 c.c. of water, into the stomach (Fig. 2) the blood pressure fell from 96 mm. of mercury to 70 mm. in the course of a minute, but immediately commenced to rise again; six minutes and thirty seconds from the commencement of the experiment the pressure was 82 mm. and eleven minutes later was practically normal.

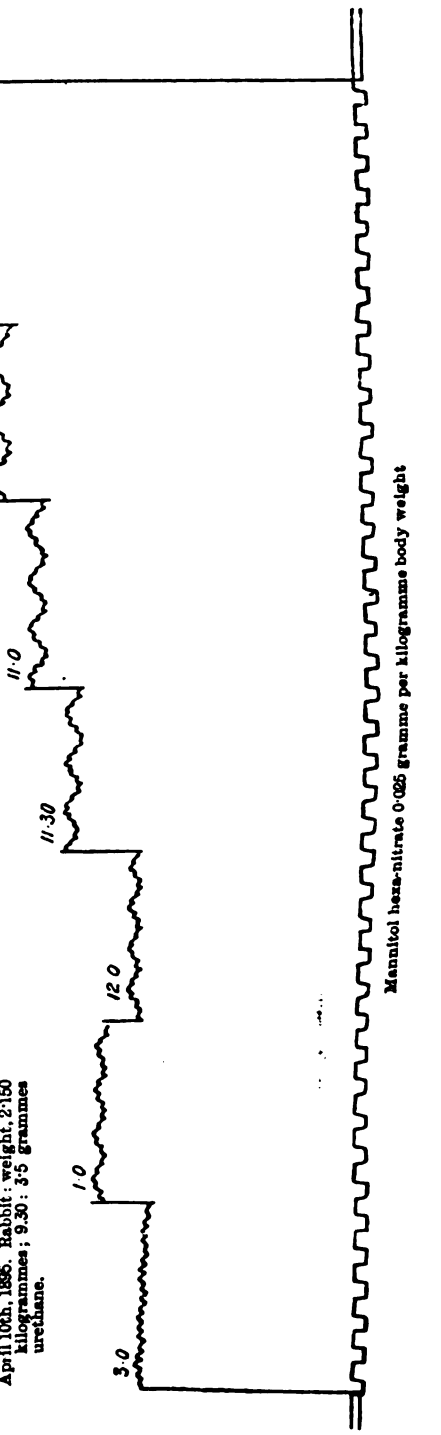

FIG. 5.

A consideration, therefore, of the action of these drugs on blood pressure leads us to the conclusion that the nitrates of erythrol and mannitol have a less marked but more prolonged action than those of glycerol and glycol, and that methyl nitrate has comparatively little action. These relations are again brought out in the various pulse-tracings before you. These have been selected from a number taken under varying conditions of health and disease, and they show in a graphic manner the fall of arterial tension and its relative duration; they are, in fact, a complement to the experiments I have described.

Pulse-tracings.—The tracing of methyl nitrate (Fig. 7) shows, perhaps, a more marked fall of arterial tension than we should expect from our previous experiments, but, as you see, the dose is an excessive one, being one thousand times greater than the glycol and glycerol nitrates, and ten times that of the solid nitrates. It is, however, essential for practical therapeutics that we should know the dose sufficient to produce a salutary effect, and hence the comparatively large dose given. The arterial tension was reduced in little more than a minute, continued to fall for sixteen minutes, and then gradually returned to normal

FIG. 6.

Digitized by Google

six hours after the administration of the drug the tension was still considerably below normal, a condition not reached until the following morning. Glycol di-nitrate in $\frac{1}{100}$-grain doses, like nitro-glycerine, quickly reduces tension. The tracings shown (Fig. 8) were taken from a young woman suffering from anæmia. The normal tension of the pulse was somewhat low, but in less than a minute it was reduced still lower, and in three minutes was hyperdicrotic. The effect, however, was very transient, and in sixteen minutes

the pulse had almost reached its normal degree of tension. Fig. 9 is one showing the effect of a corresponding dose of nitro-glycerine. It is a little peculiar in that it shows a more transient effect than usual with nitro-glycerine, but otherwise it presents the same features as those obtained by other observers. The pulse-tracings of the solid nitrates show a marked difference from those of the foregoing. Thus during the time in which nitro-glycol and nitro-glycerine present their period of greatest activity these show little or no action. After the administration of one grain of erythrol tetra-nitrate (Fig. 10) no very marked effect is noticed until fifty minutes have passed; the tension then falls gradually for another hour and a half, and afterwards as gradually returns. In the present case five hours and fifteen minutes after the administration the pulse tension had not yet reached its previous level. In the same dose mannitol hexa-nitrate produces a very similar effect (Fig. 11). The pressure in the arteries is scarcely affected until nearly an hour has passed, and it has not reached its former level even after five hours. But the relative effects of the various members of the "nitro-group" will, perhaps, be better understood by reference to a diagram (Fig. 12). This has been constructed from sphygmographic tracings controlled by perfusion and

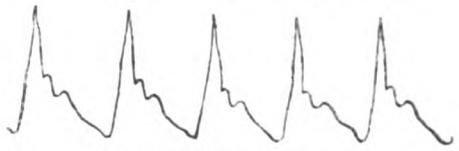
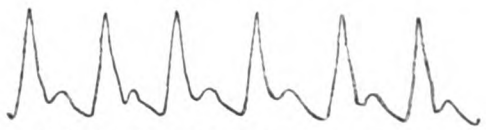
blood-pressure experiments, and although it does not pretend to minute accuracy, except as regards time relations, it will, nevertheless, serve the purpose I have in view. The time is stated in minutes and hours and the fall of arterial tension is represented by a fall from the base line which in its turn is supposed to represent the normal tension. You will see that erythrol tetra-nitrate and mannitol hexa-nitrate are quite inactive during the period of greatest activity of the other members of this series, but that their effect is markedly prolonged.



Insusceptibility.—In individual cases slight differences in the extent and duration of action of these bodies are noticed, and occasionally cases are met with comparatively insusceptible to their influence. Thus in some cases of advanced

Digitized by Google



heart disease, where the artery presents a feeling of fulness, but yet remains easily compressible (virtual tension of Broadbent), vaso-dilators have often little effect. In these cases the arteries, like the heart, have lost their normal tone, are considerably dilated, and, although possessing a sense of fulness and, on superficial examination, of resistance, are yet arteries of low tension. Coupling with this fact the tendency to fibrous tissue formation in the various organs in this condition we have some explanation of the comparative irresponsiveness of these cases. In some cases of not far advanced Bright's disease, where the tension is very high and is evidently due to causes existent in the blood, a comparatively large dose of nitro-glycerine or its allies is necessary to produce any marked reduction of tension. But, apart from such pathological conditions, we now and then come across individuals who can bear large

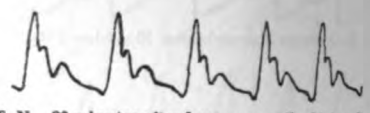
doses of these drugs with impunity (Fig. 13). Even in animals there seems to be considerable variation of susceptibility to the action of vessel-dilating drugs and particularly of the organic nitrates. The reason of this is not always clear. Habitual use tends to diminish their action, but this is obviously not the explanation in many cases. With the solid nitrates the condition of the alimentary canal is an important factor. The amount of fluid in it at the time of administration as well as its reaction will have an important influence in determining the amount of drug dissolved and therefore absorbed (Fig. 14). It may be that under the influence of the alkaline juices of the intestine these nitrates are converted into nitrites (e.g., sodium nitrite), but I am rather inclined to believe that this change, if it occur at all, takes place in the blood or in the cells which form the walls of the bloodvessels. Hitherto, however, I know only of one case, and that a man suffering from dilated heart the result of alcoholism, in which these drugs failed to have any distinct effect.



Concerning the actions of organic nitrates upon other organs I shall be brief, as they are of little practical importance. Upon the heart the direct effect of these compounds is very slight. Indirectly, owing to the diminished work consequent on dilatation of the blood-vessels, increased rapidity and sometimes palpitation

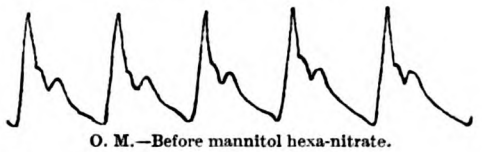
(especially after glycol and glycerol nitrates) are noticed. Certain nervous effects have been attributed to nitro-glycerine, but none have as yet followed the administration of the solid organic nitrates. The effect upon urinary excretion is practically *nil*. These bodies, as far as they have been investigated, are not diuretic.

As ordinarily administered the organic nitrates present no cumulative action. The continued use of nitro-glycerine produces a lessened susceptibility to its effect, but this has as

Digitized by Google

yet not been noticed after the administration of the erythrol and mannitol compounds.



Reviewing, therefore, the action of these compounds upon the vascular system in regard to their practical application to the treatment of disease, I think we may, at the present at least, discard methyl nitrate as being the least likely to prove of clinical value. Glycol di-nitrate, again, is so similar in action to nitro-glycerine, and, at the same time, is so much more expensive, that it also is not likely to enter into our stock of remedies. The longer acting nitrates, however, may prove of value, and I shall now turn to what I consider the therapeutic indications of these compounds.

THERAPEUTIC INDICATIONS.

From the pharmacological action of these two nitrates it would seem that the chief indication for their use is a condition where the heart is labouring under increased work imposed upon it by contracted arteries. As life advances the hitherto elastic vessels become converted into more or less rigid tubes, the fibrous adventitia is thickened, and fibrous tissue replaces, to a greater or less extent, the muscular and elastic tissues of the middle coat. As a result increased work is put upon the heart and hypertrophy results. Sooner or later, however, central or peripheral degeneration occurs: either the heart fails from the increased strain put upon it on the one hand, or causes rupture of a vessel from excessive power on the other. In disease the normal evolution may be compressed into a much shorter space of time; thickened arteries and hypertrophied hearts may be found comparatively early in life, and the final result may be the same. If by any means we can dilate the vessels we diminish the work of the heart and the pressure upon each unit of area of the artery, and thus in both ways avert the tendency to death. Our difficulty hitherto has been not so much to reduce arterial tension when we wanted as to keep the tension constantly below a certain level. Both nitro-glycerine and sodium nitrite have been used for this purpose, but their administration is attended with some inconvenience. As we have seen (Fig. 12) these drugs have comparatively little action after two hours, and it would therefore be necessary to give them at least every two hours to produce continuous low tension. Even then there would be considerable variation in the arterial pressure. By the substances I have described the tension is not brought so low, but the reduction is of longer duration, and the pressure is less liable to fluctuation. They are also, as far as I am aware, free from poisonous properties, a quality readily explained by their slight solubility. Let us consider *seriatim* the diseases in which these drugs might prove useful.

Cardiac pain.—Under this name I include all forms of pain accompanying diseases of the heart or vessels. I adopt it in preference to angina pectoris, as the limits of this disease appear to vary with different writers, and while some would almost confine it to Heberden's classic form, others would extend it to cover the whole realm of cardiac pain. The point of interest to us at present, however, is the relation of this pain to arterial tension. Is cardiac pain always accompanied by contraction of the arterial walls; and, if so, is the relation one of cause and effect? Since Dr. Lauder Brunton's discovery the question has been asked many times, but there has been no unanimous answer. Some observers state that obvious increase of tension does not always accompany heart pain, and I agree with them; but, as Dr. Leech pointed out, the increase may be more relative than absolute. In a heart weakened by disease a very slight increase of resistance may prove too much for this organ to overcome. This slight increase may be due to a general effect almost inappreciable in any one artery or to an effect localised in one or more areas. Of greater significance is the fact that vaso-dilators do not always relieve angina-like pains, especially if these occur, as I have previously mentioned, in cases of far-advanced heart disease with a low-tension pulse. In such cases morphine is of much greater value.

But what we want to know is whether attacks of anginal pain can be prevented by keeping an individual's arterial pressure permanently below its normal level, for obviously this is the only way in which the solid organic nitrates can be of service. When an attack has come on it is necessary to resort to more quickly acting drugs, and in cases of a sudden and severe nature inhalation of the fatty nitrites is advisable. For cases in which the pain is less severe and of longer duration the administration of nitro-glycerine or sodium nitrite is perhaps more beneficial. But if we can prevent the advent of these attacks a great stride ahead will have been made in the course of medical treatment. Much may be done by the exhibition of purgatives and attention to the general health, but in the majority of instances something more is needed. This something is, I believe, a vessel dilator. Hitherto nitro-glycerine and sodium nitrite have been the drugs mainly used, but, as I have already mentioned, their evanescent and varying action renders them unsuitable for this purpose. Nevertheless, I have seen cases in which the continuous administration both of nitro-glycerine and sodium nitrite seemed to prevent the occurrence of anginal attacks, and other physicians have reported similar results. In many of these cases, however, attacks occasionally developed, and it is quite possible that the longer acting remedies, such as erythrol nitrate, might have prevented them altogether.

Chronic Bright's disease.—Of the pathology of thickened arteries I do not intend to speak in detail. The most important change, and the one which affects us most closely, is the arterial thickening attending Bright's disease. As in the aged, this leads to hypertrophy of the heart, and both combined to a high-tension pulse. Sooner or later, if the patient does not succumb to uræmia or some intercurrent disease, the increased vascular strain begins to tell either upon the heart or on the vessels, often on both. Either symptoms of heart failure develop, or attacks of apoplexy of a more or less severe type occur. Previously to such undesirable terminations, headache, mental inaptitude, weariness, and similar symptoms are not uncommon, and sometimes these may be noticed with a high-tension pulse where no other direct evidence of renal disease exists. In

Digitized by Google

FIG. 12.

Comparative action of certain nitrites and nitrates.

all such cases the longer acting vessel dilators are often beneficial. I do not wish to convey the impression that I regard the thickened condition of the arteries as the primary cause of the high tension of Bright's disease. This, I believe, is due in the first instance to an impure condition of the blood, and the correct treatment under the circumstances is to rid the blood as far as possible of this impurity. Once, however, that the fibroid and muscular thickening in the arteries is produced, it becomes, as I have shown, a danger in itself. It is a condition we cannot cure, and our treatment must therefore be symptomatic. By keeping down the arterial pressure in such conditions we may not only

FIG. 13.

Showing comparatively little action after 1·25 gramme glycol di-nitrate.

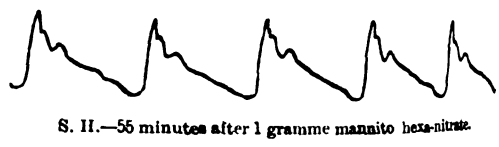
alleviate unpleasant symptoms, but may also prevent the onset of such disastrous conditions as cerebral hæmorrhage. The fibroid thickening of the bloodvessels does not annul the action of these nitrates, though it diminishes to some extent their power. Of the tracings I pass round, one series was taken from a man in advanced Bright's disease, the other is from a man who had had slight attacks of cerebral hæmorrhage. With regard to the action of these drugs upon the kidney disease itself I have little to say. I do not anticipate any beneficial action; they are not diuretic, at the same time they are not irritant to the kidneys, and, given even in acute inflammatory conditions of these organs, are not likely to produce ill-effects.

Aneurysm.—In cases of aneurysm—and I confine my remarks at present to those coming under the care of the physician—it is very necessary to keep the circulatory system as far as possible in a state of physiological rest. This is best accomplished by dilating the peripheral arteries, and for this purpose iodide of potassium has for some time been the drug most in vogue. Without detracting in the least from the value of potassium iodide in this condition, it seems to me that the nitrates of erythrol or mannitol will accomplish this end better, and will give more satisfactory results in cases not of syphilitic origin. The pain which accompanies aneurysm is not often relieved by vaso-dilators, and, therefore, I do not anticipate any benefit from the drugs I have described. Usually the pain is a pressure-effect which is only relieved by the administration of morphine.



Raynaud's disease.—Of other conditions connected with the contraction of bloodvessels Raynaud's disease is one that has been successfully treated with nitro-glycerine. If vaso-

FIG. 14.

dilators are of value in this condition it seems to me that erythrol nitrate, as tending to keep up a more constant dilatation, would be of greater value.

Dyspnœa.—With regard to respiratory conditions I do not anticipate any beneficial effects from these bodies. In various forms of dyspnœa (uræmic, asthmatic, and bronchitic) nitro-glycerine and the nitrites are sometimes of value, but they often fail to relieve. By their means sibilant rhonchi may be converted into sonorous, and sometimes may even disappear altogether, but I do not agree with Professor Fraser[6] as to the rapidity of this change. The change of pitch seems to occur *pari passu* with the fall of arterial tension, and in the majority of cases the effect is not marked. Where loud and numerous moist sounds are present even less effect is obtained.

[6] International Journal of the Medical Sciences, vol. xiv., p. 122.

Digitized by Google

Seeing, then, that the action of these comparatively powerful vaso-dilators is not very distinct, we should not expect the less powerful drugs I have mentioned to exercise much influence. They may prove of prophylactic value in the dyspnœa occurring in Bright's disease for example, but beyond that it would be useless to hazard conjectures. In cases of chronic bronchitis, however, and in other conditions where the dyspnœa is of cardiac origin, amelioration might be obtained from these compounds. In such cases the weak heart is unable to drive the blood with sufficient power along the arteries, stagnation therefore occurs in the veins, and the pulmonary system is often the first to suffer. Thus aeration is limited by the pulmonary lesions on the one hand, and the cardiac on the other. By dilating the vessels and thus relieving the heart the circulation becomes more efficient and the blood is better aerated. But under such conditions digitalis is usually of much greater benefit. Disappearance of the headache occurring in a chronic bronchitic, with full rather tense pulse, followed the administration of erythrol nitrate.

Headache.—It is also very probable that anæmic headaches occurring in patients with a high-tension pulse may be relieved by this drug, but my observations on this condition have been confined to those with a low-tension pulse, and here the results have been somewhat conflicting.

Nervous diseases.—Although nitro-glycerine has been given in many nervous affections I do not think much benefit will follow the use of erythrol or mannitol nitrates in these diseases. Migraine and neuralgia are oftentimes accompanied by reflex contraction of the bloodvessels, and the use of vaso-dilators has sometimes proved curative. The solid organic nitrates, however, are much too slow in action to be of benefit, though it is possible they may prevent attacks of migraine if administered continuously. The drugs might also be used by those who believe in the value of nitro-glycerine in epilepsy, but as I have rarely used this drug in this affection my experience on this point is limited. Other nervous diseases—epileptic vertigo, cerebral congestion, tetanus, &c.—in which nitro-glycerine has been used are not likely to yield to treatment with the nitrates under discussion.

In many other conditions nitro-glycerine is said to have proved of value. In various forms of poisoning (opium, coal gas, &c.), in vomiting from any cause (pregnancy, sea-sickness), in lienteric diarrhœa, in diabetes mellitus, in hysterical paralyses, and many other affections, nitro-glycerine is said to have proved curative or ameliorative. The pharmacological action in such conditions is difficult to understand, and in most cases the results obtained were probably coincidences. I do not think that other organic nitrates will give beneficial results when administered in these or similar affections, and therefore I do not advise the use of the nitrates under consideration in such conditions.

Dose and administration.—The dose of the solid organic nitrates may be taken as one grain; more may be given if it is thought necessary, but usually this amount will suffice. They may be taken in the form of pills or tablets or in alcoholic solution. The last method I prefer. A solution of erythrol nitrate in the strength of 1 in 60 may be made, and one drachm may be taken in an ounce of water when necessary. Mannitol nitrate is not quite so soluble, but a 1 per cent. alcoholic solution can be prepared, of which one and a half or two drachms may be taken in water. The solutions thus made are stable and free from irritating properties.

Résumé.—In conclusion, the only condition in which I think these nitrates will be of benefit is one that I have already alluded to—viz., high arterial tension. Whenever we wish to keep down the blood pressure for a length of time then I believe these nitrates will be of value. Such a result may be necessary for many reasons; a few I have attempted to indicate. It may be that the therapeutics of the drug will widen with our increasing knowledge, it may be that the limits I have laid out for them will be much diminished; but, whichever it be, I thought that a lecture devoted to the pharmacological action and therapeutic indications of a drug of which we stand so much in need would not be alien to the noble purpose which the foundress of this lecture had in view.

Although I know of no evil effects having followed the administration of these drugs, and though no such effects are anticipated, I ought to say that the research on these compounds is not yet complete.

ON THE SUPPURATIVE JOINT LESIONS OF SCARLET FEVER.

By G. BELLINGHAM SMITH, M.B. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR, GUY'S HOSPITAL; LATE ASSISTANT MEDICAL OFFICER, NORTH-EASTERN FEVER HOSPITAL, METROPOLITAN ASYLUMS BOARD;

AND

MARY D. STURGE, M.B. LOND.,
LATE ASSISTANT MEDICAL OFFICER, NORTH-EASTERN FEVER HOSPITAL, METROPOLITAN ASYLUMS BOARD.

It has long been known that joint manifestations are not uncommon in specific infectious diseases, varying from an effusion which is described as serous to the most destructive form of arthritis; but the cases in which this latter condition occurs are admittedly rare, hence it has seemed worth while to put on record the following instances which have come under our notice (and most of them also under our care) at the North-Eastern Fever Hospital of the Metropolitan Asylums Board. The infrequency of these suppurative joint lesions is shown by the statement of Dr. A. D. P. Hodges[1] that no cases occurred, during a period of three years at the South-Eastern Fever Hospital, in 7000 cases. And this would seem to be the experience of Bennet, who has stated that the rheumatic joint lesions of scarlet fever show no tendency to pus formation. Ashby[2] states that out of a series of 500 cases he met with arthritis in two only, and that in his experience the condition is rare. He alludes to one other case which he has also seen. On the other hand, in an epidemic which took place in Dublin from 1834 to 1842, this complication is described as being both frequent and malignant.[3] This suggests the possibility that its presence tends to vary with different epidemics. We have notes of nine instances in which the condition occurred, out of a series of nearly 5000 cases of scarlet fever.

CASE 1. *Scarlet fever; ulcerated throat; suppuration in elbow; broncho-pneumonia; death.*—A female child aged one and three-quarter years was admitted to the North-Eastern Fever Hospital on Aug. 10th, 1893, after three days' illness, with general scarlet fever rash, ulcerated fauces, and diarrhœa. The temperature was 103·4° F. From the date of admission until Aug. 24th her throat was continuously ulcerated, and there was much ulceration on the palate. The temperature had been generally between 101° and 104°, but occasionally a little higher, and fairly continuous in type; the respiration-rate was about 30, and the pulse averaged 130. On the 26th there was considerable swelling over the left elbow. The temperature was 104°, the pulse 160, and the respiration 50. On the 27th the elbow had increased in size; there was no definite fluctuation. The temperature was 102°. On the 28th fluctuation was obvious. Chloroform was given and the joint was explored on the outer side of the olecranon; a quantity of pus escaped, and the cartilage was eroded in places and the bone felt to be bare and rough; there was undue mobility about the joint, there being a considerable space between the bone ends. The temperature was 104°, the pulse ranged from 160 to 180, and the respiration from 50 to 60. On the 29th the patient was attacked with broncho-pneumonia, and she was unable to retain food given either by nasal tube or by rectum. On the 30th hyperpyrexia set in and death ensued. Post mortem streptococci were found in cultivations made from pus in the elbow; cultures made from the kidney showed streptococci. There was broncho-pneumonia of both lungs, and pus in the tubes. As regards albumin, a trace was found on two occasions—i.e., on Aug. 19th and 22nd. No urine was subsequently obtained for examination. The child died from septic broncho-pneumonia.

CASE 2. *Scarlet fever; pyæmia, right and left elbow; right knee; death.*—A male child aged two and a half years was admitted on Dec. 22nd, 1892, with a punctiform rash, swollen fauces, and rhinorrhœa. On Jan. 1st, 1893, there was double otorrhœa. On the 7th a septic rash showed itself, and on the

Digitized by Google

8th the right hand became swollen; the temperature being 104·5° F. On the 9th chloroform was given and an incision made over the second metacarpal on the back of the hand, and a little pus was found. The temperature was intermittent, ranging from 100·5° to 104°. On the 10th there was a swelling over the head of the left radius accompanied by wrist-drop. On the 11th an incision was made over the swelling, but no pus was found. There was paresis of the left external rectus. On the 15th there were bronchial breathing, râles, and dulness over both bases, and an ulcer on the right tonsil. An abscess over the front of the chest was opened. On the 16th fluid in the right knee was detected; there was persistent pyæmic temperature. Death occurred on the 17th. No post-mortem examination was allowed. The urine was only tested once—two days before death; no albumin was found.

CASE 3. *Scarlet fever; thrombosis of internal and external jugular veins; pus in knee and wrist; death.*—A female child aged four was attacked by scarlet fever on Feb. 3rd and was admitted on Feb. 15th. On the 21st the neck was incised, and pus was found infiltrating the tissues; there was no circumscribed cavity. The temperature ranged from 100·5° to 104° F. On the 23rd the right hand was swollen; on the 24th the temperature was 104·5°. She was very restless, and the neck was much less angry. On the 25th the temperature reached 105°; the left knee had swollen, and the patient vomited once, her pulse being very feeble. On the 26th the temperature was still 105°, and death occurred. Post mortem a large diffuse purulent infiltration of the neck was found, and thrombosis of the internal and external jugular veins at the base of the neck for a distance of about two inches; pus was discovered in the knee and wrist joints, and petechiæ in the synovial membrane of the knee. Six tubes were inoculated with pus from the left knee, all of which grew pure cultures of streptococci. Albumin was found in the urine once (the only time it was tested).

In the following three instances the joints recovered more or less completely, the results obtained being distinctly better than we at times dared to hope for, considering the serious and almost desperate state the patients were in.

CASE 4. *Scarlet fever; suppuration in elbow-joint; recovery.*—A male child aged four years was admitted on Sept. 22nd, on the fourth day of illness, with general rash, peeled tongue, and an extremely severe condition of the throat, there being much swelling of the tonsils and soft palate, with exudation on the tonsils and uvula. The temperature reached 104° F. during the first five days after admission. The throat remained swollen and ulcerated and did not perceptibly improve under treatment, and the patient seemed only to be kept alive by frequent nasal feeding, which was rendered necessary by the difficulty in swallowing. On Oct. 5th offensive otorrhœa set in. The temperature at this time varied between 100° and 102°, and the patient began slowly to improve as regarded the faucial condition. On Oct. 6th there was marked swelling about the left elbow, with effusion into the joint. Glycerine and belladonna were used as an application, and the swelling subsided a little in two days' time, the temperature falling to 99°. On the 10th the temperature rose to 102°, and the joint was much swollen again and very painful; there was undue mobility; fluctuation was felt readily on either side of the olecranon, and the olecranon process was displaced inwards, the internal condyle being obscured by the swelling. The tissues for some distance round the joint were swollen, œdematous, and brawny. Under chloroform the joint was freely opened on the outer side of the olecranon and some thin, purulent fluid escaped. The soft parts cut through were much infiltrated with inflammatory material, and the joint capsule was lax, allowing free lateral movement of the bones of the forearm on the lower end of the humerus. The ends of the bones were partially denuded of cartilage, allowing of marked crepitus in the joint. The temperature was 102°; the pulse since admission had ranged from 120 to 140, and the respiration from 30 to 40. On the 13th the throat had healed wonderfully well. A great deal of brawny swelling was still evident about the elbow; the discharge was sweet, and a drainage-tube was introduced into the joint to keep the opening through the capsule patent. The temperature had been normal since the operation. On the 17th the elbow was put up at right angles, and subsequently dressed each day in a different position. There were profuse otorrhœa and rhinorrhœa; there now developed hectic temperature, ranging from 98° to 108°, which lasted eight days, after which it remained close to normal. The heart and lungs were unaffected. On the 20th the arm was found to be tender and the joint still much swollen, the pulse varying from 120 to 160; the fauces were clean. The left otorrhœa persisted, and hot boracic baths were ordered for the arm and continued daily. On the 27th there was very little pain on moving the joint, with only a slight amount of discharge from the wound, which was healing rapidly, but a great deal of thickening still existed around the joint. On Nov. 16th the joint was freely movable, with slight grating on complete flexion; but there was some thickening about the elbow. On the 29th grating had quite disappeared, and the patient was fit for discharge, with an elbow satisfactory in all respects. There was never any albumin in the urine.

CASE 5. *Scarlet fever; nephritis; pus from wrist.*—A female child two and a half years of age was attacked by scarlet fever on Oct. 4th, 1893, and was admitted on Oct. 14th with fading rash, cleaning tongue, inflamed fauces, and rhinorrhœa. Her temperature was 100° F. On Oct. 21st the temperature rose to 102°, with swelling of the glands in the neck and vomiting. The temperature fell to normal next day, but vomiting persisted, and on the 24th albumin made its appearance in the urine as a trace; the temperature was then below normal. On the 27th the temperature had risen to 102°, and there was very marked œdematous swelling of the right hand and wrist, with great pain on movement of the hand; the swelling was most marked in the palm of the hand, and fluctuation was distinctly obtainable. Incisions were, on the 28th, made into the palm and dorsum of the hand, but although a quantity of clear fluid (due to the œdema) was drained away no pus was found, and it seemed evident that there was none in the tendon sheaths. There was a cloud of albumin in the urine. Hot boracic fomentations were used throughout. On the 31st the temperature ranged between 98° and 101°; there was much blood and albumin in the urine; the œdematous swelling had extended further up the forearm; the hand had become a little less tender on manipulation. On Nov. 1st the temperature varied from 98° to 100°. The abdomen was very distended, the spleen was felt; there were slight lumbar œdema and œdema of the feet; and albumin and blood were found in the urine. On account of definite fluctuation in the palm and sign of deep-seated pus, chloroform was again administered and the palm of the hand was again explored thoroughly; serous fluid escaped, but no pus was found and no bare bone. On account of the marked swelling in the palm of the hand the probability of there being pus about the carpal bones was not thought of, although the extreme pain on manipulation of the hand and also the presence of swelling over the wrist ought to have drawn our attention to this. The temperature went down to normal, and subsequently remained so. On the 3rd the hand was less swollen, but was distinctly very tender on manipulation; the hæmaturia persisted, but the general condition had improved. On the 5th there was on dressing the hand a sudden escape of thick, creamy, sweet pus from the lower end of an incision which passed down over the third metacarpal to the carpal bones. This pus welled up freely, and was evidently from the carpo-metacarpal joint. On the 6th there was not much pus from the wound, and no bare bone; the patient's general condition was good. From this time the swelling of the hand and wrist rapidly subsided, and on the 10th the hand was almost normal in size. There was no rise of temperature. On the 13th the albumin had ceased in the urine, and there was good movement in the wrist. The child was seen a year later (Nov. 8th, 1894), when the movement in the wrist was perfect. There was no thickening, the hand was slightly smaller than the left, and there was a little wasting of the outer interossei muscles. There had been occasional swelling of the wrist during the winter of 1893-94.

CASE 6. *Scarlet fever; nephritis; apical pneumonia; empyema; pus in hip-joint; recovery.*—A male child aged three years had had scarlet fever rash five weeks before admission to hospital on Nov. 4th, 1893, desquamating. The temperature was between 102° and 104° F., the pulse was 130, and the respiration 40; the neck was swollen and the face was puffy. The child had a cough. The urine was scanty in amount, smoky, and contained blood and a thick cloud of albumin. There was no lumbar œdema. The temperature kept high, and the respiration continued to increase until it reached 78 on the 7th, there being at the same time a pulse-rate of 150. Signs of right apical pneumonia developed. The skin was hot and dry. On the 8th

Digitized by Google

the crisis occurred, the temperature falling from 104° to 96° and the respiration coming down to 37. All this time there was scanty urine, which, when it could be measured, was found to vary in amount from seven to ten ounces in the twenty-four hours; blood and albumin persisted. On the 10th the temperature rose again to 104° F., and the respiration-rate began to increase also. Nothing very definite was found to account for this until the 14th, when at the right base signs of effusion showed themselves with impaired percussion note and weak breathing. Meanwhile the respiration-rate increased to 76, the temperature keeping up to 102° and 103°. On exploration of the chest pus was found. On the 15th, under chloroform, a portion of rib was resected and about seven ounces of thick, creamy pus escaped, an examination of which showed pneumococci. The nephritis gradually improved, the blood first disappearing and the urine becoming larger in amount. Finally, on the 22nd, the albumin ceased. On Dec. 15th the temperature had been varying from 101° to 103°. There had been marked flexion of both hip-joints for several days, with considerable swelling round the right hip, with œdema of the skin over it, and dislocation of the head of the femur on to the dorsum ilii. Under chloroform an incision was made over the great trochanter. There was very considerable bulging of the capsule of the joint; on incising this a quantity of thick pus escaped and the ligamentum teres was found to be destroyed. The joint cartilage was not impaired. The temperature after the operation kept between 100° and 101° until Dec. 22nd, and then rose daily to 100° until Jan. 1st, 1894, after which it remained about normal. On Dec. 22nd extension was put on the leg, as the head of the femur did not remain in the glenoid cavity. The patient became extremely emaciated from vomiting and diarrhœa, this condition lasting during December and January. It was with the greatest difficulty that the child was enabled to retain sufficient nourishment to just keep him alive, everything being tried. About the end of January he began to improve, but for many weeks was nothing but skin and bone. On Feb. 3rd the tube was left out of the empyema wound, and on Feb. 10th out of the hip-joint wound. The empyema wound gradually healed up, and within three months of the operation the wound over the hip was healed, but extension was still kept on. At this time measurement of the two legs gave a difference in length of from half to three-quarters of an inch. Four months after the operation the child moved the joint himself without pain, and was allowed to sit up. A month later he was walking about the ward by the aid of a chair, the movements at the hip-joint being carried out practically by the pelvis. He was sent to the seaside with a high boot. When last seen by us in November, 1894, he was in splendid condition: the chest was normal, there were about 10° of movement in the hip-joint, and three-quarters of an inch shortening. The leg was in good position, and there was no evidence that the head of the femur was out of its normal situation.

CASE 7. *Scarlet fever; cellulitis of neck; effusion into sterno-clavicular joint; dislocation.*—A female child aged fourteen years had a severe brawny neck on admission on Aug. 3rd, ten days after the onset of scarlet fever. This was incised on Aug. 4th, but the temperature remained at 102° or 103° F., and from the 10th to the 14th pyæmic symptoms were well marked. The temperature varied from 97° to 105° daily; rigors were present and free perspiration. Subsequently, although there were no rigors, the temperature kept up to 102° or 103°. The swelling of the neck slowly subsided and no pocketing of pus could be made out. On the 25th a swelling appeared over the left sterno-clavicular joint, which gradually increased in size and was tender, and the skin was reddened over it. As the inflammation appeared to be subacute, and as the temperature fell on the 27th to normal, no active surgical treatment was adopted. The swelling slowly subsided, and as it did so the inner end of the clavicle was felt to be very much thickened, and at the same time, although the distension of the joint had never seemed to be extreme, it was found that there was undue mobility resulting. On Oct. 1st the condition was as follows. The wound in the neck had practically healed. The inner end of the left clavicle was unduly movable and was dislocated upwards and inwards behind the sterno-mastoid muscle, so as to lie on the upper border of the sternum, extending inwards as far as the middle line of the neck. It could be brought down readily to its normal position, but slipped out again at once. There was no pain in the joint, and the movements of the arm were not impaired. The inner end of the clavicle was distinctly enlarged.[4]

CASE 8. *Scarlet fever; pus in ankle-joint; nephritis; recovery.*—A boy aged sixteen had a kick on the right internal malleolus about five weeks before the onset of scarlet fever. A week later he sprained his right ankle, and after walking about on it for a fortnight was admitted to the Poplar Hospital, when the swelling subsided under treatment. He contracted scarlet fever on April 9th, 1894, and was admitted to the North-Eastern Fever Hospital on the 12th. The attack of scarlet fever was slight; the fauces were a very little inflamed. The ankle was restrapped; there was no pain in it or any sign of inflammation. Six days after admission pain returned in the ankle, and the strapping was removed, when the ankle was found to be swollen and hot. As it was in much the same condition on the 27th—red, hot, swollen, and extremely painful—it was explored with a needle, and a few drops of turbid fluid were drawn off. Nephritis made its appearance on the 26th with albumin and a temperature of 101·2° F.; blood appeared in the urine on May 1st. On May 9th the condition was as follows. The ankle was much swollen, red, and œdematous; the hollows on either side of the tendo Achillis were obliterated; there was thickening over the lower end of the tibia; tenderness was most marked about the internal malleolus. On May 11th there were marked bulging on either side of the tendo Achillis and swelling round the malleoli; fluctuation was obtainable through the joint. At night when the patient dozed off to sleep there were twitchings in the ankle, with sudden pain. The temperature was 99° and the pulse 132. On the 12th the ankle was more tense. The joint was again explored, but nothing could be drawn off with the exploring syringe. There were signs of cardiac dilatation. The temperature had risen to 101°. On the 13th the foot and leg were very œdematous, and there was difficulty in detecting any fluctuation in the ankle; the lower end of the tibia was felt to be markedly thickened. A.C.E. mixture was then given and the joint again explored with a syringe, but without result. On account of the marked thickening of the lower end of the tibia it was determined to first examine this bone. An incision was made over the inner surface of the tibia extending down into the internal malleolus; the soft parts were œdematous, and the periosteum was found to be softened and thickened. It readily stripped up from the subjacent bone, and there were seen spicules and plates of new bone attached to its under surface. There was about one-sixth of an inch thickness of new bone deposited over the lower end of the tibia. The underlying bone was exposed with a gouge for about one-third of an inch in depth; the bone was soft and carious; there was no necrosis. The epiphysis was exposed; there were no signs of epiphysitis. An incision was then made into the joint just anterior to the internal malleolus, when a thin purulent fluid escaped. A finger introduced into the joint found the upper surface of the astragalus rough and devoid of cartilage. Another opening was made on the outer side just in front of the external malleolus, and the joint was syringed out, glycerine and iodoform being introduced. The wound was dressed with hot boracic fomentations. On the 21st the nephritis still persisted, and the urine was porter-coloured. During the week following the operation the ankle remained swollen and œdematous, and the swelling became more marked on its inner side behind the internal malleolus and along the inner side of the foot. On the 20th an incision was made over the swelling behind the inner ankle, and pus escaped. A counter opening was made on the outer side of the tendo Achillis. The posterior ligament of the joint was much softened, readily giving way under pressure of the finger, thus allowing free drainage backwards of the joint. A hot boracic bath was ordered. The leg was now more comfortable than it had been; the wounds discharged freely; the foot was in the bath for three hours. Blood and one-eighth albumin were found in the urine. By the 24th the time of the bath had been increased, so that on the 25th the foot remained in the bath all day and night. There was less blood and albumin in the urine. On the 26th the foot was put on a splint at night and in the bath during the day; only a trace of albumin was in the urine. The temperature ranged from 100° to 103°. By July 1st the albumin had disappeared from the urine, and the heart apex, which had been in the nipple line, wa

[4] Roswell Park and Güterbock have mentioned cases where dislocation of the hip-joint occurred without the discharge externally of pus, and De Lapersonne quotes Samuel as having seen a similar case Annals of Surgery, vol. xiv., p. 483.

Digitized by Google

returning to its normal position. The boy had been much worn out by the nephritis and the joint suppuration, but was now beginning to mend. The wounds were healing rapidly. On Aug. 1st they were all healed. On Aug. 14th, when the patient was discharged, there was considerable thickening about the malleoli. There was no movement in the ankle-joint, but no œdema, pain, or tenderness. On Nov. 3rd the patient wrote to say that he could walk on his foot without any pain, and that he would be able to follow his employment when he had recovered his strength. His ankle, he said, was quite stiff. The points of interest about this case are these:—1. The previous injury; this undoubtedly determined the seat of the scarlatinal arthritis. 2. The early onset (ninth day), with the steady but slow increase in the severity of the inflammation. 3. The subacute nature of the inflammatory process. 4. The marked thickening of the lower end of the tibia. This was not altogether, if at all, due to the injury, for it increased very markedly in the course of the inflammation of the joint. No evidence of primary disease in the bone was found at the time of the operation.

CASE 9. *Scarlet fever; ulceration and perforation of palate; abscess about great trochanter.*—A male child four years of age was admitted on May 18th, 1893, with severe scarlet fever. The temperature was 104° F. For some days the fauces were in an inflamed condition and were covered with membranous exudation. The temperature remained high, and in spite of the active treatment adopted a slough developed at the back of the throat. On June 8th there developed an oval opening at the junction of the palate on the right side with the pillar of the fauces. Rhinorrhœa was profuse. Nasal feeding was difficult on account of swelling of the nasal mucous membrane. The patient was fed by an œsophageal tube. On the 5th ulcerative stomatitis was present; on the 6th the temperature had fallen to normal; but from the 9th to the 14th the temperature was remittent, ranging from 100° to 104°. A piece of membrane over the hard palate had sloughed, exposing the bone for a space the size of a sixpenny-piece. On the 19th the temperature had been down some thirty-six hours. Vomiting was troublesome, but the opening in the soft palate had not increased. On the 21st the temperature had again risen to 104° and by the 25th was intermittent and remittent. There were considerable swelling, tenderness, redness, and œdema over the great trochanter on the left side. During the last day or two the thigh had become flexed and could not be rotated outwards except with great pain. Indistinct fluctuation was felt over the trochanter. Chloroform was given, and an incision was made down to the bone on the outer side. The periosteum was healthy. On passing a director through the insertions of the glutei muscles towards the head of the bone abundant pus was found, evidently coming from the hip-joint; the opening was enlarged and a drainage-tube inserted. After the operation the temperature fell and the child improved. The hip discharged fairly freely and healed up well, so that the patient was sent out on Aug. 22nd.

GENERAL REMARKS.

On referring to the somewhat scattered literature on these joint affections, and on comparing our cases with those already on record, various points of interest come out, which may briefly be dealt with under separate headings.

Joints affected.—In seven out of nine of our cases the affection was monarticular, and in two polyarticular. Both these latter cases died. It is generally stated (De Lapersonne and others) that of all the articulations the knee is the one that is most frequently affected in the infectious joint lesions. As far as our cases go, the evidence in support of the statement is wanting. Seven joints were affected in the upper extremity as compared with five in the lower, the elbow being the seat of trouble in 3 cases, the knee and hip in 2 cases each, and the ankle and sterno-clavicular joint 1 each. Taking the forty-five joints mentioned by different authors as being affected, we get the following results: shoulder, 2 cases; elbow, 11 cases; joints of wrist and hand, 12 cases; hip, 4 cases; knee, 5 cases; ankle and joints of foot, 10 cases; and sterno-clavicular joint, 1 case. The comparative infrequency of suppuration in the knee is well shown. Of the larger joints the elbow comes first, being affected in almost a quarter of the cases. These cases, as far as can be ascertained, all occurred in children, and it is interesting to compare the statement of Neve that in small-pox occurring in children the upper extremity is more frequently affected than the lower, and that the elbow is the favourite site of all the joints. He thinks the arm is more liable to exposure and injury than the leg in children.[5]

Condition of joints.—The conditions described by different authors have varied from thickening and injection of the synovial membrane to extreme disorganisation. Henoch says: "In all cases of the kind I have found during life the affected joints swollen, very painful, and immovable, the tissues over them being œdematous. In some instances the condition was only discovered twenty-four hours before death. We found post mortem the cavities of the joints containing greenish-yellow creamy pus, the synovial membrane very opaque, but otherwise unchanged." On the other hand De Lapersonne says: "The thickened synovial membrane very injected, the cartilages are eroded and may completely disappear, detachment of epiphyses may occur, and in one case spontaneous dislocation of the femur has occurred. Heubner and Fischer both speak of extensive disorganisation of joints. So far as our own experience goes we have met three types. 1. Cases where flail joint and dislocation followed absorption of fluid effusion into joint (see Case 1). 2. The cases in this group correspond to those described by Henoch. There exists considerable œdematous swelling round the joint together with pain (which is sometimes variable in amount) on movement. On incising the part thick, creamy pus escapes. The synovial membrane thickened, showing in some cases petechiæ. The cartilages do not show to the naked eye any signs of erosion. In these cases one would probably obtain by early incision good subsequent movement. 3. This third variety is characterised by a far more virulent condition. From the commencement there are intense pain in the joint and marked redness and swelling over it, due to inflammatory infiltration of the surrounding tissues. In fact, the inflammation seems as much *peri-* as *intra*-articular. From the interior of the joints a thin, purulent fluid is obtained, and the capsule, softened by the inflammatory process very soon after the onset, allows of undue mobility. This was very well seen in the two cases where the elbow was affected (see Cases 3 and 4). The ends of the bones are more or less extensively denuded of cartilage and rough. In one case (Case 4) there was movement which was finally quite free (and not ankylosis resulted. When, however, we consider the amount of surrounding inflammation, such a result can scarcely be expected to occur often.

Time of onset.—The time of onset of these suppurative joint lesions seems to be commonly about the third or fourth week of the disease. If we exclude Case 6, where the joint affection may be considered as secondary rather to the pneumonia and empyema than to the scarlet fever attack, and exclude also Case 8, we have seven cases where primary suppuration occurred. These seven cases give an average time of onset of 23 days (19, 17, 20, 17, 23, 31, and 38 respectively), and on examining cases published by other authors the time of onset closely corresponds. In a case published by Mauriac the joints were affected during the third week. Another three cases were rather earlier. One of them had the joint affected on the eleventh day. Of the other two one was fatal on the nineteenth and the second on the fifteenth day. Henoch[6] gives three cases where joints were affected in two weeks, two weeks, and three weeks respectively after the onset of scarlet fever. Dr. Caiger[10] relates a case where the elbow-joint was affected on the thirty-fifth day.

Association of nephritis.—The time of onset of suppuration in the joint, as we have already pointed out, is coincident about the end of the third week. This corresponds with the time of onset of nephritis. Of our nine cases five had albuminuria. This generally preceded the arthritis by a few days. In the one case where the joint affection was as early as the sixth day nephritis did not occur till the seventeenth day, about the usual period. In Dr. Caiger's case mentioned above nephritis occurred on the twenty-fifth day, and the elbow was affected on the thirty-fifth. Both lesions are probably expressive of the same general poisoning of the system.

Heart conditions.—None of our cases were accompanied by any marked cardiac lesion, nor have we seen this complication noted in other published cases.

Mode of onset.—Authorities vary in their opinions as to the origin of suppurative arthritis. Two varieties have been

SYNOPSIS OF CASES.

No.	Sex.	Age.	Onset of disease.	Condition of throat, &c.	Condition of kidney.	Onset of joint affections.	Joints affected.	Operations on joints.	Result.
1.	F.	1½ yrs.	Aug. 7th.	Much ulceration; temp. 103° F., continuous; throat very bad.	Albumin, a trace on Aug. 19th and 22nd.	Aug. 26th (nineteenth day).	Left elbow.	Opened Aug. 28th; quantity of pus; cartilage eroded; undue mobility of joint; considerable space between bone ends; streptococci in pus from joint.	Aug. 30th: Death; septic broncho-pneumonia; streptococci in cultivations from kidneys.
2.	M.	2½ yrs.	Dec. 22nd.	Fauces swollen; temp. 105° F.; rhinorrhœa; double otorrhœa; intermittent temp., 100·3° F. to 104° F.; septic rash on 16th day.	Urine tested once two days before death; no albumin.	Jan. 8th (17th day). Jan. 10th. Jan. 16th.	Right wrist. Swelling over head of left radius; Right knee. [wrist-drop.	Incised Jan. 9th; a little pus found. Incised; no pus found.	Jan. 17th: Death; broncho-pneumonia; no post-mortem examination.
3.	F.	4 yrs.	Feb. 3rd.	Purulent infiltration of neck; temp. 100·3° F. to 104° F.; neck incised on 18th day.	Urine tested once; albumin present.	Feb. 23rd (20th day). Feb. 25th.	Right hand swollen. Left knee.	—	Feb. 26th. Death; thrombosis of internal and external jugular veins; pus in knee and wrist joints; petechiæ on synovial membrane; pure cultivations of streptococci in pus from joints; no abscesses elsewhere.
4.	M.	4 yrs.	Sept. 19th.	Extremely bad throat; exudation; temp. 104° F.; offensive otorrhœa; exceedingly ill.	No albumin.	Oct. 6th (17th day).	Left elbow swollen; undue mobility and fluctuation; much swelling of surrounding parts.	Opened Oct. 11th; considerable amount of thin pus; joint capsule lax, allowing undue lateral mobility; joint surfaces denuded of cartilage.	Nov. 16th: Recovery; joint freely movable without grating; some thickening left.
5.	F.	2½ yrs.	Oct. 4th.	Moderate inflammation of fauces; temp. 100·3° F.; rhinorrhœa. Oct. 21st: Secondary adenitis; vomiting; nephritis; temp. 102·2° F.; enlarged spleen.	Albumin appeared on 24th (marked nephritis); hæmaturia; œdema of feet.	Oct. 27th (23rd day).	Hand and wrist very swollen; swelling spreading up arm.	Oct. 28th: Incisions made in palm and over dorsum; no pus found. Nov. 1st: Palm of hand explored; no pus found. 5th: Sudden escape of thick sweet pus from incision on dorsum extending over wrist-joint; pus welled up from wrist-joint; swelling rapidly subsided.	Nov. 13th: Recovery; albumin ceased; free movement in wrist; no thickening apparent a year later; occasional swelling of wrist-joint in following winter.
6.	M.	3 yrs.	*Nov. 4th.	Admitted with severe nephritis; face puffy; scanty urine; blood; temp. 103° F.; desquamating otorrhœa; pulse 130; respiration 40; signs of apical pneumonia marked on 7th; crisis on 9th, followed by empyema (pneumococci in pus); operation on 15th; nephritis well by Nov. 22nd.	Nephritis on admission.	Dec. 15th.	For two or three days child has kept both legs flexed and has complained of pain. On examination swelling round right hip with œdema of skin; dislocation on to dorsum ilii.	Dec. 20th: Oblique incision over great trochanter; considerable amount of creamy pus escaped on opening capsule of joint; head of femur on dorsum ilii; ligamentum teres destroyed; cartilage not eroded; no surrounding inflammation.	Recovery by May after severe marasmus; seen in following November; in splendid health; leg ankylosed in extended position, with ¾ in. shortening; about 10° movement in joint.
7.	F.	14 yrs.	July 24th.	Admitted Aug. 3rd with large brawny swelling left side of neck; ulceration of left tonsil; incised next day; intermittent temp. 96·8° F. to 105° F., with rigors and free perspiration; pain in head; otorrhœa; rigors ceased on 14th, but temperature kept up.	No albumin.	Aug. 25th (32nd day).	Left sterno-clavicular joints; swelling noted on this date, subacute, slowly increasing, tender, fluctuating. On 27th temture fell to normal.	—	Recovery, Oct. 1st, wound in neck practically healed; inner end of clavicle is unduly movable and is dislocated upwards and inwards on to upper border of sternum; readily reducible; inner end of clavicle enlarged; movements of arm unimpaired.
8.	M.	16 yrs.	April 9th.	Kick on right ankle five weeks ago; sprained right ankle four weeks ago; admitted to Poplar Hospital; swelling subsided on admission to North-Eastern Fever Hospital; fauces but slightly affected.	April 26th: Onset of nephritis; temp. 101·2° F.; hæmaturia &c. July 1st: No albumin.	April 18th (9th day).	Right ankle swollen and painful. April 27th: Few drops of turbid fluid withdrawn; inflammation subacute. May 9th: Much swelling; fluctuation.	May 13th: Incisions; thin pus in joint; astragalus bare; thickening lower end of tibia; soft parts much infiltrated. 22nd: Continued swollen; cavity containing pus between tendo Achillis and ankle-joint opened; posterior ligament softened; much œdema persisted; intermittent temperature.	Aug. 1st: Recovery; wounds healed. Dec. 3rd: Can walk on foot without pain; ankle is stiff; considerable thickening round malleoli.
9.	M.	4 yrs.	May 15th.	Very bad throat; membranous exudation; rhinorrhœa; temp. 104° F. June 3rd, perforation of soft palate. 14th, patch of bare bone on hard palate. July 1st, double otorrhœa. 4th, broncho-pneumonia.	No albumin.	June 21st (34th day).	Left hip-joint; swelling, tenderness, œdema, redness over trochanter; thigh fixed in flexed position. This condition became marked by June 25th. Temp. 104° F.	June 25th: Incision made over great trochanter; periosteum healthy; wound prolonged to hinder part of hip joint; abundant pus escaped; condition of interior of joint not ascertained. July 14th: Temperature fallen to normal.	Recovery; wound gradually healed and patient was discharged Aug. 22nd.

*Onset five weeks before admission.

described: (*a*) cases in which the ordinary serous arthritis of scarlet fever (scarlatinal rheumatism so called) passes on to suppuration; and (*b*) cases in which the affection of the joint is purulent from the commencement. According to Kennedy, Corrigan, Duchâteau, and Trousseau the first is the commoner variety. "The affection commences as a case of simple serous polyarthritis; then, at the end of three or four days, fever, rigors, the aggravation of general symptoms, with an increase of redness and swelling of the joint, indicate the appearance of pus in the joint."[11] Henoch, on the contrary, states that it far less commonly happens that ordinary synovitis passes into suppurative, but that the majority of cases are due to septic emboli and are purulent from the commencement.[12] Both on clinical and bacteriological grounds we should have expected to find the early serous effusion passing occasionally into the suppurative form. Ashby[13] made a great advance in our knowledge when he insisted on a distinction being made between the early and late rheumatic affections of scarlet fever, maintaining on clinical grounds that the swelling of the joints occurring early in the case was to be regarded in the light of a septicæmic condition and not as a truly rheumatic manifestation. This view has received strong support from the bacteriological side. Babes, Marie Rankin, and Lenhartz have found streptococci in the fluid withdrawn from the joints of patients presenting the early pseudo-rheumatisms of scarlet fever. We have had two cases in which death occurred shortly after the subsidence of an early serous effusion into the joints. Many sections made from the synovial membrane of this case by our colleague Dr. Scholefield, and again later by ourselves, showed abundance of micrococci infiltrating the tissues, and in one of the cases streptococci (pure cultivation) were grown from the fluid in an ankle-joint. There was no suggestion in either of the cases that the joint lesions, which were multiple, were on the point of becoming purulent. With the exception, perhaps, of Case 8 we were not able to satisfy ourselves that the purulent effusion was preceded by a serous effusion in any of our cases, thus corroborating the views held by Henoch.

Source of infection.—The majority of cases that have been described have been associated with some inflammatory condition of the pharyngeal and cervical structures. In some cases the faucial trouble is the most marked and is evidently the source of infection, as in Case 9. In several fatal cases there has been found thrombosis of the internal jugular vein. In Case 3 there was diffuse purulent infiltration of the neck, with thrombosis of the internal and external jugular veins for a distance of two inches at the base of the neck. Heubner has described a case where suppuration at the back of the right tonsil started a cellulitis of the neck which extended to the internal jugular vein, setting up septic phlebitis and thrombosis. In one of our cases (Case 6) the joint affection followed pneumonia and empyema, and in two cases where Schüller found pneumococci in the pus from the joint there had been antecedent pneumonia. Another method of infection is by the extension of inflammation to a joint from a peri-articular abscess. We have seen one case where distension of the knee-joint with a slightly turbid fluid followed the formation of an abscess just above the supra-patellar pouch. The child died before the fluid in the knee became purulent. Kennedy mentions epiphysitis as occurring at Dublin frequently in an epidemic from 1834 to 1842. In none of our cases were we able to make out that epiphysitis was the cause of the joint suppuration. This is worth comparing with the statement of Neve that epiphysitis is common in the joint affections of small-pox. In one case of acute arthritis of the hip-joint following measles we have seen the head of the femur lying loose in a large intra-articular abscess.

Treatment.—In addition to early and prompt surgical treatment consisting of free incision and drainage, we would lay stress on the advantage to be gained by prolonged immersion of the joint in a warm boracic bath. During any intervals between the baths hot boracic fomentations are preferable to dry dressings. Nasal feeding is in some cases essential in order to combat the exhaustion of the patient, and may often be used as an easy way of giving *extra* food in cases where the patient is exhausted with the effort of taking nourishment by the mouth.

Results.—With regard to results, ankylosis need not necessarily occur, even when the inflammation is so severe as to cause relaxation of ligaments and denudation of the bone ends. Dr. Caiger[14] has described a case where, following suppuration in the elbow-joint, good movement resulted. Case 4 is another example. Here, in spite of the erosion of the cartilage and the severe surrounding inflammation, free movement subsequently resulted. This we attributed to the fact that passive movement was adopted soon after the joint was opened, the arm being put in a different position each time it was dressed. Other cases where the cartilage is intact, and where there is but little surrounding inflammation, should, and do, stand a much more favourable chance of recovery with movement.

OVARIAN TUMOUR (AXIAL ROTATION), WITH RETRO-PERITONEAL CYST OF SAME SIDE; REMOVAL; RECOVERY.

BY WILLIAM TRAVERS, M.D. DURH., F.R.C.S. ENG.

ON June 5th of this year I was asked by my friend, Mr. Meredith Townsend, to see with him a woman aged fifty-one years whose history was as follows. Although not robust she had not needed medical aid since her last confinement twelve years previously. Menstruation was becoming irregular; for some little while past she had complained of an undefined uneasiness about the abdomen generally and, save in this part, had become thinner. On May 14th she was seized with an attack of acute pain in the epigastric region, with vomiting. The bowels were constipated. The temperature was normal. Beyond much tenderness, which hindered very close examination, there was nothing to be found on palpation. Under treatment the acute symptoms subsided, but she remained ill. On the night of May 29th the temperature suddenly rose to 103° F., and pain with great tenderness was felt in the right iliac region; the tongue was clean and moist. The temperature fell to 101° the following morning, but rose again to 103° in the evening. This state of things continued much in the same manner during the ensuing six days. When Mr. Townsend and I saw the patient together for the first time on the seventh day the temperature and tenderness (this latter still being fixed to the right side) had a good deal lessened. On inspection it was only noted that the abdomen was somewhat generally enlarged, not at all distended, but rather flattened. On palpation it was now evident that a cyst existed in the left side, at this time not very tense; thrill was only obtained anteriorly; there was resonance above the umbilicus, but there was ill-defined dulness in the left flank. Nothing could be felt per vaginam. We diagnosed an ovarian cyst, and on account of the right-sided pain thought it to be probably of the right ovary and to have undergone axial rotation. We urged immediate operation. The patient took three days to consider, and on June 7th the temperature again reached 102°. On the following day, with the assistance of Mr. Townsend and Dr. Schacht, I removed a cyst of the left ovary. At the time of operation the tumour had much increased in size, was much more tense and more mesial in position. There were numerous recent adhesions, which were easily swept down. The cyst contained four pints and a half of dark, chocolate-coloured fluid mingled with a good deal of purulent matter. There was one complete turn in the pedicle. The cyst wall contained a plate of bone and two teeth. On examining the abdominal cavity ere closing the wound I came upon a retro-peritoneal cyst of the same side; it extended from the diaphragm to the pelvic brim and laterally from the spine to the axillary line; it was not very tense, and the fingers could with care be passed under its margin; it lay in front of, and of course completely overlapped, the kidney. We considered it to be probably a hydro-nephrotic cyst, and as the patient had had no symptoms pointing to kidney trouble at any time, recent or remote, and the state of the pedicle and cyst contents fully accounted for the temperature, we agreed that this tumour should be left until the patient had sufficiently recovered to allow of my reaching it by a loin incision. She progressed

very satisfactorily; the temperature went down at once, and she was not troubled with sickness. She passed 16 oz. of urine the night after the operation, of sp. gr. 1023, acid, and containing no albumin, but 1·2 per cent. of urea. On the second day she passed 16 oz. of dark chocolate-coloured urine (that passed both before and after being quite normal), which on skilled examination was said to be "deeply coloured by hæmoglobin, with dense deposit of blood, mucus, pus, &c., innumerable crystals of calcium phosphate, some casts, numerous red blood-corpuscles, leucocytes in every stage of transition, and some renal epithelium." A smaller quantity of this type was again passed on the third day, but on no other occasion. The stitches were removed on the eighth day, when the wound was practically healed. She was keeping so well and improving so markedly in general health that, although the second cyst was notably increasing in size, whilst carefully watching her, I was disposed to wait yet a few days ere submitting her to the second operation, which probably meant a nephrectomy. On the night of the sixteenth day from her first operation the temperature began to rise, but she herself seemed well, and the cyst, which had been still slowly increasing in extent, gave rise to no pain or tenderness, the urine, too, keeping normal. On the night of the eighteenth day it somewhat suddenly reached 104°. On the day following (June 25th), with the aid of the same assistants as before, I adopted the lumbar incision recommended by Mr. Henry Morris, and easily came down upon the left kidney and a somewhat tough-walled sac, closely approximated; the cyst was slightly connected with its surroundings by recent adhesions. Breaking these carefully down with the finger, I at length found that the cyst and kidney were entirely separable, being in no way connected. Having tapped the cyst with an ascites trocar and removed four and a half pints of dark greenish fluid, I without the least difficulty shelled it out from its bed. There was very little hæmorrhage, only one ligature being called for, and that in the abdominal wound. A large-sized rubber drainage-tube was put in deeply and the wound closed with silkworm gut. Save for the small aperture made by the trocar, the cyst proved watertight; its inner surface, over about a third of its extent, was coated with a thick, shaggy lining of recent organised lymph. The patient's recovery from the day of operation was uneventful. The temperature became normal on the fifth day and never rose again; she passed three pints of urine of normal character within the first thirty hours, and it has continued so since. The wound discharged very freely for two days and then gradually slackened. The stitches were removed on the fourth day, as was also the tube, as the edges of the wound showed some slight redness, which, however, then at once disappeared. At the end of eight days she was removed to a sofa in the daytime, and she is now convalescent and has gained flesh markedly.

Remarks.—The chief interest in this case centres round the retro-peritoneal cyst. I have carefully searched the literature at my disposal and cannot note a like case. It appeared on palpation (and the rare opportunity of effecting this intra- as well as extra-abdominally here existed) to be of renal origin; the character the urine presented, too, on the second and third day after the ovariotomy pointed seemingly to grave kidney distu bance. The position of the tumour and its consequent capability of acting as a kidney irritant or mere mechanical obstruction to the ureter must be borne in mind. It is also a singular fact that these two tumours should have been present at the same time in the same patient without giving rise to earlier or more marked symptoms.

Phillimore-gardens, W.

THE HANTS COUNTY ASYLUM.—A new block for idiots has just been completed at the Hants County Asylum at Knowle, near Fareham. It is already occupied by thirty-seven patients. During the past year a committee of the county council have had under consideration the question of installing a water-softening apparatus to deal with the hard water which is obtained from the new pumping station, and a scheme for the carrying out of the work is promised for the next meeting of the county council. The separation financially of the Isle of Wight from the county of Hampshire proper has just been carried out, and in future patients from across the Solent will be charged at the same rate as other out-county inmates of the asylum. There has been an increase, in common with the country as a whole, in the numbers of inmates, the total at present being 1083—492 males and 591 females.

SEQUEL OF A CASE TREATED BY KOCH'S TUBERCULIN, WITH THE RESULTS OF THE NECROPSY.

BY J. G. SINCLAIR COGHILL, M.D., F.R.C.P. EDIN.,
SENIOR PHYSICIAN, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.

IN 1891[1] I described in detail the successful treatment of ten cases of pronounced pulmonary tuberculosis by Koch's method in the Royal National Hospital for Consumption, Ventnor, during a period of sixteen weeks. These cases were repeatedly examined by, and the treatment was conducted under the observation of a large number of, medical men unconnected with the hospital. The subsequent history of these cases has been carefully noted, and reports of their condition obtained at frequent intervals from competent observers. At present, after a lapse of over four years, eight of these ten patients are in excellent health, with every evidence of complete arrest of the pulmonary lesion, and are following their ordinary avocations. One of them has been serving for nearly three years in one of the battalions of Her Majesty's Foot Guards. Of the other two cases, one—referred to in my report as No. 7—died eighteen months after leaving the hospital from a return of symptoms referable to fæcal accumulation, similar to that which caused the tuberculin inoculations at the hospital to be suspended from the 19th to the 31st March. This attack was in nowise associated with tuberculosis.

The remaining case, described in my report as No. 10, was inoculated, I may say, almost under protest, both lungs being affected, the tuberculous process so acute, advanced, and extensive, and the general conditions also most unfavourable. He pleaded so earnestly that as he had only a few months, perhaps weeks, to live, he might be allowed the chance of improvement for the sake of his wife and young children, and I must confess I very reluctantly yielded. After leaving the hospital the patient took up his residence in Ventnor. The case was therefore kept continuously under my own observation and examined from time to time until the fatal termination, which occurred very suddenly from cardiac failure on Nov. 17th, 1894. A post-mortem examination was made within eighteen hours, and it is most interesting to compare the conditions then ascertained, with the physical signs and other symptoms described in my report as previously noted during and after treatment by tuberculin innoculation. For the purpose of this comparison I must briefly recapitulate the principal details of the case from the above mentioned report. The patient was a man aged forty-five years with a strumous diathesis. His height was 5 ft. 5¼ in., and weight 8 st. 4 lbs. He had been ill for three years. Severe and persistent cough began two years previously. There had been night sweats for twelve months, with loss of appetite, and progressive emaciation. There had been no hæmoptysis. Before innoculation he expectorated daily an average of two ounces of thick, greenish-yellow sputum, nummular, and containing abundant bacilli. The evening temperature reached 101° F., and in the morning was subnormal. The specific gravity of the urine was 1022, acid, with a slight mucous deposit, and a haze of albumin. The pulse was 102, soft and compressible. The first cardiac sound in the mitral area, and the second sound in the pulmonary area, were reduplicated. Respiration was 25 per minute. The physical signs in the lungs were as follows. There was flattening at both apices, above and below the clavicle, but more so on the left side, where movement was also more restricted. On the right side in front the percussion note was impaired to the third rib, with expiration prolonged, vocal resonance increased, and distant amphoric breathing under the clavicle. Behind, the note was impaired at the apex, expiration was lengthened, and increased vocal resonance to spine of scapula. In front of the left lung there was absolute dulness to the third rib and impaired to the fifth rib. There was loud superficial cavernous breathing with pectoriloquy to the lower margin of the third rib, with moist crepitations over the whole lung. Posteriorly there was absolute dulness at the apex and in the supraspinous fossa; in the latter there was amphoric breathing but no crepitation.

The patient was inoculated with 0·001 gramme of tuberculin at 10 A.M. on Dec. 27th, 1890; the highest temperature was 102·5° at 9 P.M. The pulse was 116. The breath rate was unaffected, but the cough was severe, and the expectoration, which was very frothy, increased to three ounces in twenty-four hours. The urine became flocculent on cooling and showed a phosphatic deposit with alkaline reaction and sp. gr. 1020. On examining the chest, in addition to the previously noted sign, fine crepitations could be heard all over the left lung posteriorly. By the 29th these crepitations had disappeared, and the patient stated that he he "had coughed up less the last twenty-four hours than for the last two or three months," but bacilli were still found even more thickly clustered in the sputum. By Jan. 5th, 1891 (nine days), he had lost 4 lb. 4 oz., and this loss of weight occurred during the course of the earlier inoculations in seven of the ten patients under treatment. From this I inferred that the dose of tuberculin was still too large, and the reactions injuriously excessive, and in all subsequent inoculations I adapted the amount of tuberculin, so as to produce merely an indication of reaction, and to this I mainly attribute the exceptional success of the treatment in my hands. By Jan. 19th the loss of weight was recovered, and the increase went on rapidly and continuously. On Feb. 8th the fifth inoculation of 0·003 gramme was followed by moist râles or crepitations, exaggerated on coughing, over the whole of the right lung in front and the upper third behind; and in the left lung anteriorly there were crepitations over the base and friction round the lower limits of the vomica; at the apex behind there were also crepitations. The development from time to time after inoculation of peculiarly superficial, small, dry crepitations, especially over the bases of the lungs posteriorly, was noted in nearly all the cases. These crepitations conveyed to the ear the impression of some pleuritic origin, as if the pleura was hyperæmic or the pulmonary tissue immediately under it was affected in some way. The association, also frequently noted after the earlier and larger inoculations, especially of severe pains in the joints, abdomen, and head would point to some similar concurrent cause, but not, however, of a tuberculous nature. Their disappearance was usually as sudden as their onset and as complete. By April 14th this patient had had twenty-two inoculations—the highest, 0·065 gramme—amounting in all to 0·4625 gramme of tuberculin. The greatest reaction, 104·6°, was reached on Jan. 8th, after 0·002 gramme In this case I was much impressed with what seems almost to amount to a law—that, in proportion to the extent and activity of the tuberculous lesions, the greater and more prolonged is the reaction to the same doses of the lymph; hence, the more advanced and active the pulmonary lesion the greater the necessity for proportionally smaller doses and longer intervals in its administration. On leaving the hospital on April 16th, 1891, his weight was 9st. 3lb., being a gain of 13lb. since Dec. 25th, 1890, and a gain of 17lb. 4oz. since Jan. 5th. The patient had improved remarkably in condition and appearance. He expressed himself as "feeling wonderfully better." He had no night-sweats. The cough was easier; but the expectoration varied greatly, and on the whole was less in quantity and not so purulent and nummular. Bacilli, however, were still abundant. The appetite and digestion were excellent, and the functions regular. His pulse was stronger and fuller. The first sound of the heart was reduplicated in the mitral, and both sounds were reduplicated in the aortic and pulmonary areas. The flattening of the lungs was more marked, and movement more deficient under both clavicles, especially at the left side. In the right lung, anteriorly, the note was dull to the nipple. There was increased vocal fremitus, amphoric breathing under the clavicle, and pectoriloquy, with a few scattered crepitations; and posteriorly dulness to the inferior angle of the scapula with a very few crepitations. In the left lung the note from the apex to the nipple was more impaired than on the right side, with loud superficial amphoric breathing and pectoriloquy, with crepitations only on coughing, also a few small crepitations at extreme base. Posteriorly there was dulness to the spine of the scapula, obscure amphoric breathing and exaggerated vocal resonance in the supra-spinous fossa, and towards the base a few scattered crepitations. The patient, with his family, took up his residence in Ventnor. I inoculated him at intervals for six weeks, by which time the temperature, now normal, ceased to respond to the tuberculin. The moist crepitations throughout the lungs gradually cleared up, and the other physical signs indicated that only the smaller vomica at the right apex was quite dry, the larger at the left apex still affording moist crepitations on coughing. The only cough was that necessary to raise daily, and mostly in the morning, the six to eight nummules which now constituted his daily expectoration. The patient, who could be seen daily walking smartly about Ventnor and the neighbourhood, came to me every three months or so to report himself and to be examined. The sputa always contained bacilli, the physical signs remained the same except when an occasional catarrh declared itself, which, however, always passed off. The patient all the time used a respiratory inhaler with guaiacol, eucalyptol, and chloroform, and took, with occasional interruptions, capsules of five minims of guaiacol (three daily) which he said "always improved his wind." On Sunday, Dec. 11th, 1894, he had been at morning service and had afterwards partaken of a hearty dinner at table with his family. On the 13th I was asked to see him "as his breathing was very bad." I found him suffering from extreme dyspnœa, with an anxious, drawn face, but able to speak rapidly and explain his symptoms. The pulse was hardly to be counted, it was so faint and compressible. The heart sounds were also very faint, and the apex beat was hardly perceptible. I prescribed a mixture of tincture of digitalis, tincture of sumbul, ether, chloroform, and compound tincture of cinchona co., to be given at frequent intervals, with appropriate nourishment, &c. Next day I found him very much better. I visited him the next day and one, when he seemed further improved. The following day I also saw him, and he wrote out some directions and signed some documents with a steady hand, but I had not left him above an hour when he all at once raised his hands, laid them on his wife's shoulders, and then suddenly expired.

Necropsy.—The post-mortem examination was performed eighteen hours after death by Dr. Lewis and Dr. Frost, resident medical officers of the Royal National Hospital, Ventnor. They made independent notes which are embodied in this report. The body was found to be fairly well nourished. The right lung was adherent, and the pleura much thickened over the upper half of its extent; the left lung was adherent superiorly for about two-thirds of its extent, and there were also smaller adhesions to the pericardium and diaphragm. There was, however, no difficulty in removing the lungs from the thoracic cavity without rupture of their substance. The whole of the upper lobe of the left lung was occupied by a cavity with thick fibrous capsule and lined by a pyogenic membrane with pus-moistened walls. The middle lobe was adherent to the upper and also entirely excavated, and the capsule and lining presented similar characters. These vomicæ did not communicate, and each opened independently into a bronchus. The right lung contained a caseous nodule surrounded by a thick fibrous capsule. The whole upper third of this lung was occupied by a cavity with an extremely thick fibrous wall. The lining membrane had no pus on its wall—indeed, it seemed almost dry; it communicated with a small bronchus. This vomica is the one recognised in the original examination and referred to in the report as of older standing than the excavation in the left apex, and as also being in a condition of arrest. The lungs of both lungs were much congested hypostatically, and contained a few capsulated caseous nodules scattered throughout their substance. The heart was extremely small, anæmic, and its walls much thinned; the right side was dilated and full of blood. The valves were quite healthy.

Remarks.—If the physical signs and symptoms of this patient as ascertained by competent observers before treatment, the phenomena developed during its course, and its condition at its termination, and subsequently, be compared with the state of the lungs as revealed at the necropsy, there can hardly be any hesitation, I think, in ascribing the arrest of this extensive area of acute pulmonary tuberculosis to judicious tuberculin inoculation. This case confirms me in the opinion I have always held, and still hold, that tuberculin has potent therapeutic efficacy in the treatment of tuberculosis when used judiciously and with caution in dose and under conditions adapted to each individual case. In the Continent Koch's method has survived the unscientific and regrettable haste which, after the great promise of its inception, too prematurely condemned it. No less an authority than Dr. Armand Ruffer, when writing to me lately on another subject, told me that he was much impressed with what he saw of this treatment on the occasion of a recent visit to Berlin.

Ventnor, Isle of Wight.

EXOPHTHALMIC GOITRE.[1]

BY JOHN HILL ABRAM, M.D. LOND., M.R.C.P.,
ASSISTANT PHYSICIAN, STANLEY HOSPITAL; ASSISTANT TO THE PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE; PATHOLOGIST, ROYAL INFIRMARY, LIVERPOOL.

DURING the last two years I have had under my observation five cases of exophthalmic goitre, and I have had the exceptional experience of two necropsies—one on a case of my own and the other on a case of Dr. Davidson at the Infirmary. I shall divide the remarks I have to make into three groups—viz., (1) the symptoms; (2) the morbid anatomy and pathology; and (3) prognosis and treatment.

1. *Symptoms.*—The onset may be acute or chronic, the course short or prolonged over years. The earlier symptoms are associated with the cardio-vascular system and consist chiefly of a persistent tachycardia. Occasional attacks of palpitation are present. Physical examination reveals a diffused cardiac impulse, with enlargement of the area of cardiac dulness. Functional bruits are common. The arteries in the neck are dilated, and visible pulsation in them is common. The radial pulse is frequent and of low tension; the frequency may be 150 to 200 per second. Goitre follows and consists of a firm enlargement of the gland, usually more marked upon the right side. The goitre is painless, and, in my experience, is not pulsatile. A rough systolic murmur is usually audible in the neighbourhood of the gland. Exophthalmos may be a very late symptom. Other eye symptoms are defective descent and retraction of the upper lid. In one case I noted a symptom first recorded by Joffroy—viz., a loss of the contraction of the frontalis muscle associated with the sudden upward movement of the eyes. The pupils in my cases, with one exception, were not dilated. To the so-called cardinal symptoms another should be added—viz., muscular tremor. It was present in all my cases, and is, I believe, a constant and early symptom of the disease. The tremor has been thoroughly investigated by Marie,[2] who states that it may be best brought out by getting the patient to hold the arms in the extended position. The narrow excursions and the rapidity (8½ per second) distinguish the tremor from other forms; that of alcoholism, which most resembles it, may be recognised by the irregularity both of time and excursions. The general features of the disease are familiar, and may be, therefore, very briefly given. They are emaciation, anæmia, irregular rises of temperature, flushings and sweatings, diarrhœa, and excitable mental state, passing on to actual insanity. Amenorrhœa is a constant feature in women. Diminution of the electrical resistance of the skin is said to be a constant phenomenon. In a few cases general enlargement of the lymphatic glands has been observed, and in both the necropsies I have made the lymphoid follicles in the intestines were swollen. Dr. Hunt informs me that he has twice operated for enlarged tonsils in cases of Graves' disease. In both cases the enlargement took place after the onset of the latter. Rarer symptoms are various forms of paralysis, glycosuria, albuminuria, and œdema. The termination may be in recovery or death from exhaustion or syncope.

With this brief account of the clinical features I pass on to consider my second group.

2. *Morbid anatomy and pathology.*—The older theories of Stokes and Graves (primary cardiac) and Marshall and Taylor (pressure on nerves and vessels of neck) have been long abandoned. The sympathetic theory must, I think, now be given up also. The tachycardia and the vascular dilatation at first sight suggest a lesion of the sympathetic nervous system. On closer examination it is found, as Gowers points out,[3] that this theory involves the assumption of (*a*) a partial affection, or (*b*) a twofold action—viz., a stimulating one upon the accelerating fibres for the heart and a paralysing one upon the vaso-motor fibres—a double-barrelled action the probability of which is rather remote. Again, if there were a sympathetic lesion we should expect dilatation of the pupils to be a common symptom, whereas it is rare. It was only present in one of my five cases. Moreover, the sympathetic system in the neck has been found to be normal in the vast majority of the fatal cases. In thirteen cases recorded by Lewin[4] it was normal in all. It was normal in both my cases. A much more probable theory is one which locates the lesion in the central nervous system, and more especially in the medulla. The association of arterial dilatation with increased frequency of the heart's action is in harmony with Marey's well-known law that "there is an inverse ratio between pulse frequency and blood pressure in consequence of their relationship to a central mechanism." Filehne, and Durdufi, in repeating Filehne's experiments, have shown that division of the restiform body gives rise to symptoms closely resembling those of exophthalmic goitre. There is no doubt, too, that in some cases, more especially the acute ones, lesions have been found in the medulla—e.g., increased vascularity by Greenfield[5] and myself, hæmorrhages by Müller,[6] Hale White, Stewart and Gibson,[7] and abscess by Stewart and Gibson.[8] The usual absence of anatomical changes and the undoubted presence of a marked neurotic inheritance led Charcot to regard the disease as a neurosis, and to this phase of the nervous theory I shall allude again. For my own part, I fail to see how a lesion in the medulla can give rise to the psychical and paralytic symptoms so commonly met with in this disease. It is probable that the cardio-vascular phenomena are due to a disturbance of the medullary centres, but that this disturbance is secondary and not primary. The nervous system theory is still accepted by many writers (Mannheim[9] and others), but the latest, and at present, I think, the most satisfactory, theory is the one which attributes the disease to a primary lesion of the thyroid gland. In considering the affection from this aspect the thyroid gland must be dealt with first. The examination of the goitre in my two cases revealed a condition which was in striking contrast to that usually described. The condition I found corresponds closely to that recorded as present in their cases by Stewart and Gibson,[10] Greenfield,[11] O. Hezel,[12] Joffroy,[13] and Putnam.[14] The thyroid gland was enlarged; the alveoli were small and apparently more numerous, they were packed with cells, and the colloid material was absent. In one of my cases (acute) there were masses of leucocytes at the points of entrance of the larger vessels. In chronic cases an overgrowth of connective tissue has been present, with some tendency to cyst formation. It will be noticed that in this description there is no allusion to any marked increase of vascularity. Is the goitre a vascular one? From the clinical side I must say that in my five cases repeated examinations failed to detect any expansile pulsation in the goitre, and the histological examination of my own case and under Dr. Davidson's care confirms me in the belief that the goitre is not a vascular one. Of course, some increase in vascularity is necessarily present in an over-active gland, but my point is that there is nothing approaching an aneurysmal condition, and therefore the goitre in Graves' disease is not clinically a pulsatile one.[15] The marked thrill and bruit present in these cases are due to vibrations in the main thyroid arteries and not in the gland itself. It is important to note that the histological characters described above are present even when the gland during life is not appreciably enlarged—a point of great interest in connexion with cases of persistent tachycardia, which many observers would class as *fruste* examples of Graves' disease. Greenfield[16] compares the histological characters to those seen in an active mammary gland, and suggests that the thyroid gland in these cases is in a state of over-activity. Some support is lent to this suggestion by the fact that the gland tissue in Graves' disease bears a close resemblance to the thyroid tissue in early life, when the gland is supposed to be in a state of great activity.[17] Assuming, as I think is permissible, that the thyroid gland

[16] THE LANCET, Dec. 16th, 1893.

[17] Professor Sherrington informs me that after partial thyroidectomy the remaining gland tissue assumes the character of that seen in Graves' disease—a fact which gives additional and strong support to Greenfield's suggestion.

Digitized by Google

is over-active in these cases, it has yet to be shown that excess of thyroid secretion can give rise to the symptoms of the disease. The symptoms of thyroidism in the human subject bear a very close resemblance to those of exophthalmic goitre—emaciation, sweating, frequent pulse, tremors, excitable nervous system, and exophthalmos[18] have all been observed. Again, the contrast between the symptoms of myxœdema, which it is universally acknowledged are due to the absence of thyroid secretion, and those of exophthalmic goitre, which it is suggested are due to an excess of thyroid secretion, is very marked, as will be seen by the following comparison:—

	Myxœdema.	Exophthalmic Goitre.
Thyroid gland	Atrophy	Hypertrophy.
Sweating	Absent	Copious.
Temperature	Subnormal	Often raised.
Sensation	Of cold	Of heat.
Electric resistance of skin	Increased	Diminished.
Pulse	Infrequent	Frequent.
Mental and bodily state	Sluggish	Excitable.

Further support is lent to the thyroid gland view by the fact that in some twelve cases recorded by Ord and others the symptoms of Graves' disease have been followed by those of myxœdema. The intimate connexion between the thyroid gland and exophthalmic goitre is still further emphasised by the favourable results following operations which lessen the amount of secreting gland tissue.

—	Number of cases.	Improvement.	Recovery.	Death.
Putnam[19]	51	34	13	4
Wette[20]	30	28	—	—
Lemke[21]	8	3	5	—
Krönlein[22]	8	8	—	—
Kocher[23]	39	39	—	—
Tillaux[24]	2	2	—	—

It seems, therefore, that there is much probability in the view that exophthalmic goitre is a thyroid disease and that the symptoms are due to an excess of thyroid secretion in the blood. Mr. Edmunds,[25] on experimental grounds, seems to incline to the sympathetic theory, but upon this I need not touch again. He raises the question as to whether the disease is due to an excess of normal secretion or to a perverted secretion. No doubt the injection of cocaine produces many, if not all, of the symptoms of exophthalmic goitre, but it appears to me that, inasmuch as normal thyroid juice will give rise to all the symptoms of the disease, it is unnecessary to assume the existence of any poison akin to cocaine.

Before dealing with the question of prognosis and treatment I must add a word with regard to the eye symptoms. Exophthalmos is frequently a very late symptom, and is, I believe, due to the dilatation of the retro-bulbar vessels. In one of my cases it disappeared during an attack of diarrhœa, to return when the diarrhœa ceased. In the fatal cases I examined no appreciable increase of intra-orbital fat could be made out, and it has always been a matter of wonder to me why this suggestion should have been made in view of the fact that emaciation is a marked feature of the disease. The external ocular muscles were pale, but not obviously fatty; Müller's muscle I could not find in one case. The mechanism of Von Graefe's and Stellwag's symptoms is no doubt nervous, but as to the exact nature thereof I have no suggestion to offer.

3 *Prognosis and treatment.*—Gowers[26] says "that in few diseases of equal severity and corresponding apparent gravity is the prognosis so uncertain, and that in well-marked cases little or no improvement has followed the most careful treatment." With the first clause of this statement all will agree, but it is probable that the thyroid theory of the disease may lead us to reconsider the second. Briefly put, the routine treatment has consisted in rest in the recumbent posture and quiet surroundings, and in four of my cases this was sufficient to enable the patients to go back to work. The late Mr. Denton Cardew strongly recommended electrical treatment, and Nothnagel speaks very high effect of mountain residence. Drugs, in my do but little good, although it is interestir the reputed value of belladonna from its well-kn on the salivary glands. Although I have n experience to offer, yet it seems to me, from th have submitted, that in operations intended to di amount of thyroid gland tissue there exists a better prospect of affording relief, if not cure, t jects of Graves' disease. Two operations seem to the test of trial. They are (1) partial thyroidect right lobe only has usually been removed, in all th my list, with the exception of Kocher's. (2) Ligat thyroid arteries. This was the operation selected and is based upon the experimental work of Tarch has shown that ligature of the thyroid arteries atrophy of the gland. In Kocher's cases three four main arteries were tied.

A few words must be added with regard to the e side of the question. There is little definitely k I shall just touch upon the two points which are en in all the text-books. The first is that in the ma not in all, of the cases there is a marked neuroti ance. I made this out in all my cases. The secon emotional disturbance is a prominent exciting caus was certainly not so in my own cases, and it is probe in the cases attributed to emotional disturbance the has been present, though unnoticed, and that emotio caused an exacerbation of symptoms which brou patient under observation. The intimate relationship the thyroid gland and the central nervous system h established beyond all doubt by the experimental Horsley and others, and, therefore, it is impossible absolutely that the thyroid changes are dependent primary nervous lesion. It seems probable tha admitting this, the symptoms are brought about by e thyroid activity.

In conclusion I would urge that the important link chain of phenomena called "exophthalmic goitre" thyroid gland, and that it is to the breaking of this li we must direct our efforts for the removal of the sym of the disease.

A NOTE ON

CYSTIC DEGENERATION OF THE MAM WITH THREE CASES OF "RECURREN ON THE OPPOSITE SIDE.

BY HERBERT SNOW, M.D. LOND.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON.

ALTHOUGH one not seldom hears a breast tumour s of as "a simple cyst," I desire to point out that such a very rarely, if ever, occurs in women verging on middle when the organ is entering its devolution epoch. In young a dilated milk-duct is often seen as the resu obstruction, and may well be thus described. After the of thirty-four cyst formation is, in my experience, invari due to a general aberration in the devolution of the e parenchyma, not merely of one but, as the follo cases show, of both mammæ. There may be found a single cyst of appreciable size; with this, how are always associated numerous others, possibly ha larger than a pin's head, uniformly distributed throug the gland tissue. If not operatively interfered with the dition may continue until the entire mamma becom congeries of cysts, within which, sooner or later, "in cystic vegetations," carcinomatous or sarcomatous, deve It is brought about, like cancer, by any emotiona mechanical hindrance to the natural processes, whereby mammæ pass to their obsolete phase. When there redundant formation of white fibrous tissue between cysts the tumour is spoken of as a "cystic fibrom but there is no essential difference between this and simpler cystic degeneration. It is best when operat carefully to remove the whole breast tissue, and questioned, as commonly happens, about possible "rec rence" to give a guarded prognosis so far as concer the remaining organ. The point that we have here to d with a general and not merely a local lesion of t

Digitized by Google

parenchyma is hardly, I think, sufficiently appreciated by the profession at large; but unless attended to may involve the practitioner in some disrepute.

The first case was that of a woman aged forty-eight, married, with two children, who was admitted to hospital in October, 1894, with an induration at the root of the right nipple of one year's duration. She complained of some lancinating pain. There had been no injury, but chronic ill-health, and latterly she had been unfortunate in business. The tumour appeared as large as a hazel-nut. The patient thought there had been discharge from the nipple. There was no gland enlargement. Upon removal it was found to be one large cyst, with the remaining parenchyma pervaded by minute cysts; there were no vegetations and no malignant indications. The patient has just (October, 1895) had the left breast removed for an exactly similar condition, the right side remaining, of course, healthy. The second case was that of a woman aged thirty-five, single, sent by Dr. Garry Simpson of Acton in August, 1892. She was a spare, neurotic woman with a fluctuating tumour in the left breast, which had been noticed six weeks, as large as a pigeon's egg. On removal one large cyst filled with turbid fluid was found; the whole breast tissue was full of tiny cysts. In July, 1893, the remaining organ was found to be slightly lumpy. In August, 1895, a distinct cyst the size of a bean was apparent in the lower segment, and removal was advised. The third case was that of a widow aged forty-six, who had three children; she was seen in November, 1893. In the right breast was a large prominent globular tumour the size of a hen's egg, freely movable, hard, and solid to the touch. The patient was neurotic through much worry. On removal a multilocular cyst with solid round fibroma as large as a marble was found. There was no malignant tissue. The patient reappeared in July, 1895, with a tumour the size of a walnut, rounded and hard, in the left mamma. It quickly increased in size from augmentation of the fluid contents, and has just been removed, proving wholly cystic.

Gloucester-place, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SYMPATHETIC OPHTHALMIA WITHOUT EVIDENCE OF MICRO-ORGANISMS.

BY W. J. COLLINS, M.D., M.S. LOND., F.R.C.S. ENG.,
FELLOW OF THE UNIVERSITY OF LONDON.

A WOMAN aged sixty-five years was admitted on Aug. 20th, 1894, into the London Temperance Hospital. There was a history of failing vision for two years, for which she had been treated at another hospital, where an operation for cataract had been performed on the right eye in April, 1894. The operation was unsuccessful, and the eye had remained painful and almost blind. Three weeks prior to admission the sight of the left eye suddenly became dim, and there was much ocular pain. She was seen for the first time as an out-patient on Aug. 16th, and was told to go in at once, but unfortunately she did not present herself until Aug. 20th. On admission the right eye was painful and red, and the media were not clear. The site of the old coloboma was occupied by a reddish-yellow mass, and the remainder of the iris was fixed by a dirty bloodstained effusion. There was only perception of light. The left eye was red, watery, and painful; the cornea was clear, but the pupil did not act to light. Owing to the presence of a nearly mature cataract the vision was only perception of light and hand reflex. The right eye was at once excised and belladonna fomentations applied to the left. Subsequently she developed a smart attack of iritis in the left eye, with swelling of the eyelids, which, however, yielded slowly to treatment. She was discharged with the left eye in a quiet condition, but with some posterior synechiæ. Owing to the cataract the vision could not be further tested. The excised eye was placed in Müller's fluid and handed over to Mr. Cargill, surgical registrar at King's College Hospital, who made a careful search for micro-organisms by various methods, and mounted several sections of the eye. The sections show the coloboma blocked with leucocytes; the lens, or remains of the lens, is present; the deeper layers of the ciliary body and choroid are crowded with small, round lymph cells, and the sheath of the optic nerve, especially in the neighbourhood of the porus opticus, exhibits similar infiltration. Mr. Cargill assures me that elaborate searches for micro-organisms yielded absolutely negative results. Here, then, was a case of sympathetic iritis in which the exciting eye, excised *flagrante delicto*, yielded no evidence whatever of particulate infection by the most thorough methods of investigation. The mystery of sympathetic ophthalmia is not yet solved. During the height of the neurotic school of thought we were directed to the ciliary nerves for some kind of reflex causation; the humoralists, however, looked to the lymphatic sheath of the optic nerve as the path of infection. In obedience to the germ theory domination the ciliary nerves have of late been less accused, and the lymphatic sheath has been regarded as merely providing a path along which bacteria might proceed. The case I now record will serve to indicate that this explanation may not be all-sufficient. The reflection that sympathetic ophthalmia is in some way merely corollary to the law of symmetry and the recollection of the selective powers exerted by similar tissues may supply a more fruitful working hypothesis.

Albert-terrace, N.W.

NOTES ON A CASE OF APYREXIAL ENTERIC FEVER.

BY W. RUSSELL, M.B. ABERD., D.P.H. LOND.,
RESIDENT MEDICAL OFFICER, NORTH CITY FEVER HOSPITAL, LIVERPOOL.

A BOY aged thirteen years was admitted to hospital as suffering from enteric fever. His parents said that he had been ailing for over a week. On admission he presented a typical typhoid look of prostration, lying on his back with his arms lying loosely by his side. The pupils were dilated and he had a circumscribed flush on each cheek; his tongue was covered with a dirty-white fur. The abdomen was slightly tympanitic, and there were two rose-coloured spots disappearing on pressure. There were no lung complications, and all that the patient complained of was a feeling of being tired. There was no diarrhœa at any time during his illness. He was fed solely on milk. The temperature on admission was 100° F.; it fell to normal next day, and remained so for ten days, during which time his tongue was still heavily coated and the typhoid appearance was well marked, when the temperature rose to 103·2°, and he passed about three ounces of blood, his temperature falling in twenty-four hours to normal. Next day there was another rise to 101·4°, and he passed about four ounces of blood, his temperature subsiding to subnormal and continuing so for eighteen days. He was then allowed to sit up in bed, but kept strictly on a milk diet, as his tongue, notwithstanding stomachic medicines, had not perfectly cleared up. Two days later the temperature rose to 101°, and then a typical typhoid temperature continued, with numerous typhoid spots and very foul tongue. Gradually his tongue began to clean, and he was discharged from the hospital four weeks later. The point of interest in the above case was the fact of the patient presenting typhoid symptoms, tongue, spots, hæmorrhage, &c., notwithstanding that his temperature remained normal or subnormal, except before the hæmorrhage occurred, and after being allowed to sit up in bed.

Liverpool.

RADICAL CURE OF HYDROCELE BY INJECTION OF PERCHLORIDE OF MERCURY.

BY N. WHEATCROFT HOLMES, L.R.C.P., L.R.C.S., L.M. EDIN.
LATE GOVERNMENT MEDICAL OFFICER IN WEST AND SOUTH AUSTRALIA, AND HOUSE SURGEON TO THE MANCHESTER SOUTHERN HOSPITAL FOR DISEASES OF WOMEN AND CHILDREN.

THE result of the following case proved very satisfactory. A man aged sixty-eight years, suffering from diabetes, had a large fluctuating swelling of five years' duration in the scrotum on the right side, pyriform in shape, with a smooth regular outline. There was no impulse on coughing, and it was non-translucent by transmitted light. On Sept. 22nd I first made an exploratory puncture with a hypodermic needle and

Digitized by Google

drew off some clear fluid, then by tapping with trocar and cannula I further evacuated twenty ounces of serum of a dark-brown colour with numerous flakes. With the intention of washing out the tunica vaginalis without withdrawing the cannula I connected a large glass syringe by means of a piece of fine indiarubber tubing and injected an ounce and a half of a solution of perchloride of mercury (two-thirds of a grain to six ounces); but as this did not return upon pressure, and not wishing to make a further puncture with a larger trocar, I let it remain. On Sept. 23rd the scrotum was slightly inflamed and œdematous, and there was a temperature of 101° F., necessitating the patient remaining in bed. The temperature rose to 102° on the 25th, but by use of evaporating lotion it became normal on the 26th, when the patient got up. On Sept. 28th there was slight orchitis, with some fluid in the sac (no doubt the perchloride of mercury solution injected). On Oct. 1st the orchitis and fluid were subsiding. On Oct. 30th the fluid was all absorbed; there was no refilling of the sac, only a slight enlargement of the right testicle, which was the case when the patient was young. The scrotum appeared to be contracted, and the patient felt quite comfortable. The object in this case was to avoid the operation of excision of the sac, the condition of the patient not admitting of it, and to obtain a radical cure without pain, inflammation, or necessity of the patient going to bed. No doubt the retention of the perchloride of mercury solution set up a little more inflammation than would have occurred, otherwise the patient need not have remained in bed the three days. Three years have now elapsed, and all is well and the patient comfortable.

Tachbrook-street, S.W.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A CASE OF RADICAL TREATMENT OF UMBILICAL HERNIA IN A CHILD.

(Under the care of Mr. EDMUND OWEN.)

THIS case is published as a proof that there are even exceptions to the rule that reducible umbilical hernia in a child should never be submitted to operation. We consider that to this rule there are *very few* exceptions, and any surgeon who does operate should be prepared, like Mr. Owen, to give his reasons for departing from the recognised practice. We must, therefore, draw attention to the fact that this patient was kept under observation in a hospital bed for five weeks, and full consideration was given to her case before the operation was performed. We do not consider that the operation itself presents any great danger in the hands of a skilled operator, but this form of hernia is so very common in children that if it were once admitted that operation might be done for, it many cases would be subjected to the treatment which would be most likely to effect a speedy cure. Some patients would die (although the percentage of deaths might be a low one) who would have made a satisfactory recovery had the usual treatment of this form of infantile hernia been patiently carried out. For the notes of this case we are indebted to Mr. G. R. Baldwin, F.R.C.S., surgical registrar.

An ill-nourished female infant aged fifteen months was admitted to the Hospital for Sick Children, Great Ormond-street, on July 2nd last. The history given was to the effect that she was born with a rupture at the umbilicus, and that it had been steadily increasing in size ever since, until it had attained the size of a small hen's egg. It was reducible with the greatest ease, the opening into the abdomen being large enough to admit the index-finger and having a firm, circular border. She had a high, square forehead, a natiform skull, and an ill-developed nose. There was, however, no confirmation whatever of the existence of the congenital taint which these features suggested, and as the wrist-ends of the radii were greatly enlarged the general feebleness of the infant was ascribed to rickets. She had been specially sent into the hospital in order that the hernia might be operated on, the persistent trial of less radical measures having failed to produce any improvement. For five weeks she was kept in bed and carefully dieted, the protrusion being kept back with a flat pad; but at the end of this time (Aug. 7th), preparations having been duly made, chloroform was administered, and an operation was performed as follows. The bowel having been returned, an incision was made, skirting the base of the tumour down to the peritoneum. The peritoneum was then cut off flush with the front of the abdomen, integuments and sac being taken away together. The circular opening in the peritoneum was then sewn up, and the edges of the skin wound were approximated by stitches which, inserted wide of the cut surface, traversed the fibrous wall of the abdomen and made all secure. A week later the dressings were changed, the wound being soundly healed and giving no impulse on the patient crying. On Aug. 29th she was taken home, to all appearances perfectly cured.

Remarks by Mr. OWEN.—If the evidence of the parents can be relied on, the foregoing was an example of that somewhat rare form of umbilical hernia which consists in a protrusion of a piece of bowel into the interior of the umbilical cord—a true *congenital umbilical hernia*. For the most part, the variety of umbilical hernia met with in infancy and childhood is that in which, on account of the umbilical cicatrix being too soft and weak, the intra-abdominal pressure first causes a bulging at the scar and then an absolute emigration of the bowel—an *acquired umbilical hernia*. On seeing an umbilical hernia, the first thing to be done is to find out why the protrusion has occurred. It may be that it was acquired because the infant had been perpetually straining with vomiting, in which case, if a flat pad is strapped over the aperture and the food and feeding are properly regulated, a cure may be gradually effected. Sometimes, again, the hernia is caused by straining set up by a tight foreskin, by diarrhœa, constipation, a rectal polypus, or by whooping-cough. In such cases a radical operation is obviously out of the question. Then, again, in the rickety child, when the bowels are distended by the accumulation of gases and the linea alba is frayed out and the interval between the recti abdominis is widened, the umbilical scar must needs be weakened, and the occurrence of an exomphalos is invited. In these circumstances the administration of repeated doses of rhubarb and soda, together with careful dieting and supervision, may effect all that is needed. But when the causes of the rupture are obscure, when no clear "indications" for treatment are discoverable, when the abdominal aperture is large and the flat pad and strapping have failed, a radical operation is not only justifiable but necessary. At the present time surgical ingenuity seems to be specially busy in designing new methods of procedure.[1] But it by no means follows that, because a surgical procedure is new and original, it is necessarily "improved," and, so far as my experience goes, the simple and ordinary operation briefly referred to above leaves, as a rule, nothing to be desired. After operating I apply no strapping, band, or belt; if the operation has been done with due care it should need no supplement, though it is prudent to keep the child in the horizontal position for a few weeks subsequent to the healing of the wounds. Provided that the child has not been operated on "straight away," but has been subjected to a sufficient preparatory treatment, the cure of the exomphalos should not be the cause of the occurrence of a rupture in the inguinal region, but I can quite understand that if the inflated intestine of a rickety child has been thrust back into an unreceptive abdomen a secondary rupture might occur. However, such an event is outside my personal experience. Lastly, supposing that both gentle and radical measures fail to effect a cure on a child's umbilical hernia, will the exomphalos persist during school-life and manhood? I think not. On the contrary, I do not remember ever to have seen an umbilical hernia in adult life except in the case of extremely obese women and men whose abdominal cavities and lineæ albæ have been taken possession of, and seriously weakened, by an ever-increasing deposit of fat.

Before submitting this clinical record I thought it my

[1] See La Semaine Médicale, March 6th, 1895; also Revue de Chirurgie, April 10th, 1895.

Digitized by Google

duty to have the child up for examination. I saw her on Nov. 6th and regretted to find that on Saturday, the 2nd, during a violent fit of coughing, a slight protrusion had taken place. There was a small aperture running transversely through the linea alba, behind the scar of the operation, and, though it is insignificant compared with the size of the original opening, its presence is disappointing. On re-reading my report and observations, however, I have the satisfaction of finding that the procedure carried out was termed "radical *treatment*," not "radical *cure*." Treatment and cure are, unfortunately, not always synonymous terms.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Discussion on Posture in its Relation to Surgical Operations under Anæsthetics.

AN ordinary meeting of this society took place on Nov. 12th, Mr. HUTCHINSON, President, being in the chair.

The adjourned discussion on the paper by Dr. Frederic Hewitt and Mr. Marmaduke Sheild on Posture in its relation to Surgical Operations under Anæsthetics was resumed by Dr. SCANES SPICER, who said that posture was most important in operations upon the throat and nose. He held that whenever possible it was better to do these in the consulting-room chair under a local anæsthetic. In the recumbent position illumination was most difficult. He had never seen a bad result from the administration of chloroform to children in a sitting posture. In removing laryngeal growths from children he had had chloroform administered in this position, and, further, had used cocaine locally to produce a more complete anæsthesia. The Trendelenburg position was useful in cases in which the larynx had to be split. He asked if any special precautions were considered necessary for the maintenance of a free air-way in the sitting posture and how long after the production of etherisation would the anæsthesia last.

Dr. SANSOM thought that the paper had a direct bearing on the reduction of the present terrible mortality from chloroform. Dr. Hewitt and Mr. Sheild deprecated the sitting and semi-recumbent positions, as did the Hyderabad Chloroform Commission, and this was more for the avoidance of circulatory than respiratory failure. Dr. Leonard Hill's experiments were of extreme value, as showing that there was a real danger from syncope in the administration of chloroform. This did not occur through direct paralysis of the cardiac centre, but through a special paralysis of the vaso-motor mechanism governing the abdominal vessels; this was part of the phenomena of shock. Reviewing the practice of chloroform administration from the early days there were two schools of thought. On the one side, Syme, Lister, and others held that there was no danger from syncope from chloroform administration, but from failure of respiration only. On the other hand, Snow and others thought that this doctrine was dangerous, and experiments were made to prove this view. Thirty years ago he himself recorded a large number of experiments on animals and he proved that respiration was nearly always the first to cease; a large number, however, showed evidence of failing heart rather than failing respiration. During the present year up to the end of October forty-eight deaths from anæsthesia had been recorded; forty-one of these were due to the administration of chloroform, and in thirty-nine the death took place during the administration: this seemed to him to be a great waste of life. Failure of the respiration brought about in an indirect way paralysis of the heart. The lessons derived from experiments on animals could not in this instance be directly and without qualification applied to man; for the cardio-vascular reflexes in the two were not the same. He did not personally know of any condition of heart disease which of itself excluded the administration of an anæsthetic. It appeared to be the strong hearts rather than the weak which were more likely to succumb. A tendency to syncope had been observed in athletes after influenza, and to such hearts chloroform might be harmful. He concluded by urging the necessity of watching the circulation as well as the respiration.

Mr. SPENCER WATSON, speaking of the sitting posture for nose and throat operations, said that he was against the use of chloroform for these, and restricted the anæsthesia to that which could be produced locally. At the Royal Eye Hospital it was so arranged that each bed could be wheeled to the operating theatre, and this obviated movement of the patient immediately before and after the operation.

Mr. BRAINE criticised the recommendation of Dr. Hewitt and Mr. Sheild that the patient should not be first anæsthetised and then moved afterwards, and said that he did not agree with it either from the anæsthetist's or the patient's point of view. The patient should preferably be anæsthetised on the side, the under hand being placed beneath the pillow. If there were any struggling the upper hand was placed beneath the under elbow and thus the patient would remain quiet. The after-removal of the patient to the theatre for the operation would not induce vomiting if the anæsthesia were sufficiently deep. With Clover's crutch the centre of the strap should be placed over the centre of the vertebra prominens and the free ends brought over each shoulder in front. He agreed that the lateral posture was the best when the patient was coming round after the operation.

Sir WILLIAM DALBY said it was a matter of common knowledge that he had removed adenoids in the sitting posture under an anæsthetic since 1883. He continued to prefer this attitude, which caused no trouble or anxiety. He criticised certain statements in the paper with reference to faulty positions of the head and urged that the opinions expressed with regard to these positions should not be equivocal.

Dr. SEMON remarked that it was in operations upon the throat and nose that the greatest danger arose. He added that the recommended posture, with the head turned on one side, was not the correct one for goitre. In some large goitres the trachea had become converted into a soft and flexible tube. If such a trachea were turned one-fourth round on its own axis, death on the table might occur, and had occurred before the operation had actually commenced. In chronic laryngeal obstruction patients often carried their heads in one position, which was most comfortable for them. If the head were extended respiration would stop; in such cases the anæsthesia should be induced in the position most comfortable for the patient, as less likely to excite reflex spasm. The great point about operations such as those for adenoids was not to anæsthetise too deeply.

Dr. LEONARD HILL remarked that it was not often that a physiologist could turn out work of immediate utility in practice. He referred to the methods of restoring animals from syncope. In chloroform collapse the heart was dilated in all cases. Deaths from anæsthesia occurred in the physiological laboratory. If the thorax were immediately opened after such a death the heart would be found in a condition of diastole, and the subjects might continue to respire for some moments after the heart had ceased to beat. In such a condition pressure on the abdomen only increased the mischief by tending to thrust more blood into the over-full heart; the only chance was to rhythmically compress the heart itself in order to get good blood from the lungs into the coronary arteries. He did not think that respiratory failure was of importance in connexion with chloroform administration in animals. The condition of cardiac dilatation never occurred with ether. The condition of vaso-motor paralysis varied much in animals. If the vaso-motor system were out of order gravity would take the blood down to the abdomen. In some animals the vaso-motor system would actually over-compensate when the animal was moved from the horizontal to the vertical position. In the human being, if the vaso-motor system were weakened, as after influenza, this vaso-motor influence could be readily demonstrated. Severe operative lesions of the abdomen might cause vaso-motor paralysis and syncope; pressure on the abdomen would restore such a patient. A large crucial incision in the abdominal wall, by allowing the bowels to hang down, abolished the vaso-motor constriction, which could be restored by supporting the abdominal contents. Mere mechanical pressure on the abdomen was good, therefore, in cases of shock, but not in instances of chloroform dilatation. In these latter the animal should be placed in the horizontal position and the heart rhythmically compressed, this being accompanied by artificial respiration.

Dr. BOWLES insisted on the importance of gravity in assisting the keeping open of a free air-way in chloroformisation. Pulling forward the tip of the tongue would not raise the

Digitized by Google

base of that organ, but on turning the patient to one side gravity would cause the base of the tongue to fall away from the back of the pharynx. In cases of embarrassment from chloroform administration the heart was poisoned from an overdose, and this made the question of the dose and its measurement important. The Marshall Hall method of restoring the apparently drowned squeezed the heart and thus acted in the manner Dr. Hill had recommended.

Mr. GEORGE ROWELL was unable to dissent from any of the generalisations in the paper. The air-way was more narrowed when ether was used, owing to the congestion of the mucous membrane which that drug produced. In many deaths under chloroform the impediment to the breathing was the first bad sign. A good many deaths had occurred when the head was quite extended and the incision just commenced in the operation of tracheotomy. He related the details of a case of removal of an epithelioma from the mouth of a man aged seventy, and of a case of thyroid tumour in a woman accompanied by dyspnœa, both of which were operated upon in the semi-recumbent position; in both of them signs of collapse were at once arrested on temporarily resuming the recumbent position. He held that the condition of the respiration should be the chief guide in practice, and that Lawrie's cases without a fatality went far in support of this. Ether was given in the sitting posture every day for dentists, and it was quite exceptional for trouble to arise. In the Guy's Hospital reports for 1892 he had advocated compression of the heart in chloroform dilatation.

Dr. SILK thought that a more scientific and practical way of dealing with the subject would be to treat of it according to the particular operation proposed to be performed and the particular anæsthetic proposed to be given. A great distinction should be drawn between the induction and the maintenance of anæsthesia. The impossibility of swallowing was more often due to propping open the mouth than to extension of the head. If the head were turned to one side the chin should be kept well up. He asked Dr. Hewitt and Mr. Sheild what position they recommended for cerebral operations.

Dr. HEWITT, in reply, said the phenomena attributable to faulty head posture had been by others attributed to other causes. Ether could be given in the sitting posture with safety, and the length of time during which its effects would last would depend upon the amount administered. He thought that the true explanation of the collapse in cases of softened trachea was still to be given.

MEDICAL SOCIETY OF LONDON.

Addison's Disease treated by Supra-renal Extract.—Temporary Resection of Upper Jaw for Naso-pharyngeal Growth.—Congenital Imbecility with Deficiency of Chest Wall and Cardiac Disease.—Wiring of Patella in Elderly Man.—Periostitis of Tibia.—Spina Bifida Occulta.—Postero-lateral Sclerosis.—Nephrectomy for Renal Injury.—Secondary Syphilis.—Double Ptosis with Crossed Diplopia.

A CLINICAL meeting of the above society took place on Nov. 11th, Sir JAMES CRICHTON BROWNE, President, being in the chair.

Dr. SANSOM showed a man aged twenty-five years who was the subject of Addison's Disease and who had been treated by Supra-renal Tabloids. He was admitted into the London Hospital last July suffering from noises in the head, nausea, and vomiting. He was a labourer by occupation and had been in good health until twelve months before admission. The discolouration of the skin had been noticed for seven months, and photographs were shown to illustrate its condition at that time. The patient was given one tabloid of the supra-renal extract three times daily at first, and two tabloids daily later. In a month an extraordinary improvement was noticed, and he had gained fourteen pounds in weight. Under a previous arsenical course he had lost a pound and a half in a fortnight. There was no history of tuberculosis in the family, but there was a little impaired resonance under the left clavicle, and there had also been slight hæmoptysis.—Dr. ALTHAUS asked if sugar had been found in the urine. In a case in which he had administered the gland extract improvement was noticed at first, but later a fatal result followed.—Dr. SANSOM, in reply, said that there was no sugar in the urine, but there was a slight trace of albumin.

Mr. STANLEY BOYD showed a patient on whom he had performed Temporary Resection of the Upper Jaw. The man was forty-nine years of age, and when admitted to hospital he could not breathe through the right nostril. There were profuse epistaxis, proptosis, epiphora, diplopia, and anosmia. There was no elevation of the orbital floor or disturbance of the line of the teeth, and the hard and soft palates were normal. The naso-pharynx was found to be blocked by a growth of benign nature on the right side. The head was turned to the left, the carotid artery was exposed in the neck, and an assistant kept his finger on it to control hæmorrhage if necessary. The usual incision for resection of the jaw was then made, the upper incision extending outwards to the mid-zygoma; the nasal process of the superior maxilla, the zygoma and the malar bone were then divided and the hard palate sawn through, but the soft palate was retained intact. The superior maxilla with the cheek was then turned outwards, and a gap an inch wide was found to exist at the posterior nares. The growth, which was found to spring from the region of the sphenoidal sinuses, was cut away with scissors, and the dura mater was exposed at the bottom of the wound. The superior maxilla was replaced, wire sutures applied, and an iodoform plug inserted in the sphenoidal sinus. There had been no recurrence of the growth, and the diplopia and epiphora had disappeared.—Mr. MANSELL MOULLIN mentioned that he had devised a somewhat similar operation (which was described in full in THE LANCET of Sept. 30th, 1893), and he had found when looking up the literature of the subject that thirteen other methods had been described. He did not ligature the carotid artery, but he performed a preliminary tracheotomy and had no trouble from hæmorrhage. Mr. Macready had modified this operation by dealing differently with the hard palate flap.—Mr. WALSHAM had split the soft palate and then cut away the hard palate, which obviated the necessity of moving the superior maxilla, and there was no external scar. Another objection to the resection method was that there was sometimes a good deal of trouble with the lacrymal duct, and permanent swelling of the lower lid had also occurred.—Mr. WALLIS said that he had removed a large naso-pharyngeal growth by the route Mr. Walsham recommended, having previously performed tracheotomy on the patient. The growth was attached to the internal pterygoid plate, was easily seen, and it was removed with but little hæmorrhage.

Mr. HAROLD showed a patient with Congenital Deficiency of Chest Wall. He was sixteen years of age, and the youngest of four children. He was five years old before he attempted to walk, six before he began to speak, and ten before he was understood by strangers. He was undoubtedly mentally deficient. Below the fifth rib on the left side there was a deficiency of rib cartilages, so that the præcordial area was unprotected, and the heart could be felt on palpation to rotate under the hand. There were double apical and basic murmurs present.—Dr. FLETCHER BEACH agreed that the patient was a congenital imbecile, and added that the mother had suffered from a severe shock during early pregnancy.—The PRESIDENT said that in these cases there was usually more than feeble-mindedness present.—Dr. SHUTTLEWORTH said that congenital heart mischief in this class of cases was not uncommon. The diagnosis of the nature of the cardiac lesion was, however, a matter of difficulty and was often not confirmed post mortem.—Dr. SANSOM remarked on the disproportionate hypertrophy of the right ventricle which was present. The arrested mental and physical development pointed to an aperture in the inter-ventricular septum, and this condition was accompanied by mitral and perhaps aortic regurgitation from super-added rheumatism.

Mr. F. C. WALLIS showed a man aged seventy years who had suffered from a Transverse Fracture of the Patella, and on account of a tendency to bronchitis he wired the bone. The lower portion of the divided patella was broken into three; one loose piece he removed, and the others were partly extruded through the untorn aponeurosis over the bone, and could not be returned except on division of this structure. The patient was allowed, owing to cough, to sit up in bed on the third day, and made a good recovery.

Mr. WALLIS likewise exhibited a boy who, after acute Periostitis of the Tibia, developed suppuration of the knee-joint. Though pus was present in the joint and drainage maintained for six weeks, yet recovery with good movement resulted.

Dr. LEONARD GUTHRIE showed a boy with Spina Bifida Occulta and Paresis of the Leg. The child was aged ten; there was a depression opposite the first sacral lamina, which was deficient, and in the mid-line there was a post-ana

Digitized by Google

dimple. The left leg was slightly shortened and wasted, and this had commenced nine months ago. The foot assumed a position indicating paralysis of the interossei, and sensation was impaired to heat and to the effect of the battery, the reaction of degeneration being present. The condition of the limb, he thought, was due to peripheral neuritis of the posterior tibial nerve, which was subjected to some traction near its root.—Dr. SAVILL suggested that the absence of sensation of heat and cold indicated the presence of syringo-myelia.

Dr. LEONARD GUTHRIE also showed a patient aged twenty-seven years who had been in the National Hospital for the Paralysed and Epileptic, Queen-square, in 1894 with grave nerve symptoms, which had improved greatly under mercury and iodide of potassium. Later spastic paraplegia had developed, which passed away under the same treatment. His condition, which had varied from time to time, was that of marked unsteadiness of gait, not like tabes or spastic paralysis, but more resembling that of cerebellar disease. The knee-jerks were increased, but there was no ankle-clonus, the ocular movements were perfect, the sphincters normal, and there was no pain or sensory disturbance. There were no signs of cerebellar disease and no history of syphilis. He suggested that the lesion was a peri-vascular inflammation somewhere in the mid-dorsal region.—Dr. ORMEROD did not agree with the name given to the disease; he thought that the patient was possibly suffering from disseminated sclerosis.—Dr. GUTHRIE, in reply, agreed that the case was not one of ordinary type. The fact that the patient had so considerably recovered was against the diagnosis of disseminated sclerosis.

Mr. SWINFORD EDWARDS showed a man aged fifty-five years who was admitted into the West London Hospital in February, after having fallen from a third storey window and spiked himself on the railings below. There was a comminuted fracture of the eleventh and twelfth ribs, and a wound in the loin exposing the kidney, which was bleeding. The kidney was removed, and by the fifth day the normal amounts of urea and urine were passed. The wound suppurated for a month, but a good recovery ultimately ensued.

Dr. SAVILL showed a girl aged fifteen years suffering from a Secondary Syphilitic Eruption which somewhat resembled erythema iris.

Dr. SAVILL also showed a boy aged thirteen years who had Double Ptosis and Crossed Diplopia, which came on suddenly three weeks before. There had been a sore-throat before the advent of the ocular symptoms. He thought the cause to be a central lesion at, or in front of, the corpora quadrigemina, involving the inner aspects of the third nerves.

CLINICAL SOCIETY OF LONDON.

Suprapubic Cystotomy and Prostatectomy in cases of Multiple Calculi.—Intussusception through a Patent Meckel's Diverticulum.—Fragilitas Ossium.—Cerebral Tumour healed by Internal Medication.

AN ordinary meeting of this society was held on Nov. 8th, Dr. BUZZARD, President, being in the chair.

Mr. MANSELL MOULLIN read a paper on Suprapubic Cystotomy and Prostatectomy in two cases of Multiple Calculi. The patients were both men over sixty years of age and heavily built. One had already passed five uric acid calculi spontaneously, and the other three. In the former, when the bladder was opened above the pubes, eighteen more calculi were found lying in the post-prostatic pouch, all of them approximately of the same size and shape, rather larger than those that had been passed by the urethra, and ground into a more or less cubical shape by friction. Each was a distinct calculus with a nucleus of uric acid, not the fragment of a larger one broken up. In the second case there was only one stone, about the size of a penny, but a good deal thicker and fitting accurately in the pouch. In each case there was a considerable median upgrowth of the prostate into the bladder behind the urethral orifice. This was excised with scissors and cutting forceps, a mass approximately of the size of a walnut being removed, and the route made level and as smooth as possible. No constitutional disturbance followed in either case. The wounds healed rapidly without leaving a fistula, and urine was passed per urethram in about three weeks. Convalescence was a little delayed in one of them by an attack of epididymitis that followed the introduction of a catheter. Union was greatly helped by means of a truss (shaped something like a double inguinal truss) devised by Mr. Birch of Clapton and so arranged as to press the deep surfaces of the wound together. Mr. Moullin brought forward these two cases as illustrating a principle suggested some time since by Mr. Mayo Robson that in cases of multiple or recurrent calculi, associated with median vesical enlargement of the prostate, the operation of election was suprapubic cystotomy with excision of the intra-vesical portion of the upgrowth, so as to obliterate as far as possible the post-prostatic pouch. Lithotomy or lithotrity without this addition is in such cases little better than a temporary expedient. In men of a certain time of life who had suffered from multiple calculi it was more than probable that as they grew older fresh ones would either form in the bladder or descend from the kidney, and then the operation had to be repeated. There could be no doubt that in both the above cases, had the prostate not been enlarged, no operation would have been required; the calculi would have been got rid of while still small enough to pass down the urethra. One patient had already got rid of five in this way, and the other of three. Unhappily the rest did not escape at once; they fell back into the post-prostatic pouch and increased in size until they could not be passed. Nor did the removal of the projecting portion of the prostate add materially to the gravity of the operation so long as the urine was acid. The high rate of mortality with which suprapubic prostatectomy was credited was due to the fact that it had nearly always been performed as a last resource in hopeless cases where everything else had been tried and had failed, where the patient's strength was completely broken, and where the wall of the bladder was infiltrated with septic organisms from long-continued suppurative cystitis. In cases in which the urine was acid and was kept aseptic the prognosis was entirely different.—Mr. GOLDING-BIRD said that even in advanced years it was safer to clear the bladder by the suprapubic route, whether the growth of the prostate was removed or not. The risk was less than with lithotrity.—Mr. BUCKSTON BROWNE held that excision of the middle lobe of the prostate did add materially to the risk. So far as he could judge—and his experience in these matters was great—the second case might have been equally well treated by lithotrity.—Mr. MANSELL MOULLIN, in reply, said that the gravity of excision depended entirely upon the amount of the prostate that was removed. Ablation of the middle lobe, provided that the urine remained acid, did not add much to the gravity of the procedure, and the result was better inasmuch as calculi coming down afterwards were easily expelled from the bladder in a natural manner.

Mr. GOLDING-BIRD read notes of a case of Intussusception through a Patent Meckel's Diverticulum. The case was that of an infant four weeks old through whose umbilicus soon after birth a red protrusion was seen, and through which motion passed. Shortly before coming under observation the protrusion had increased and altered in character. Its appearance in all respects corresponded with that of an intussusception, and this diagnosis was given, it being further regarded as one of protrusion of the distal, and not proximal, bowel through the open umbilicus. It was not possible to undertake anything operative, and the child shortly died; the necropsy showed the diagnosis to have been correct. He remarked on the rarity of these cases and referred to a paper by Barth which dealt exhaustively with them. That surgeon quoted a very similar case to the one now brought forward, but the intussusception was from the proximal into the distal gut (Meckel's diverticulum), and not in the reverse direction. Mr. Golding-Bird considered his case as, in all probability, unique, and pointed out that the chance of recovery could only be given by a laparotomy, with probably resection of the affected gut, but his patient was too collapsed to permit of so grave an operation. All the cases of complicated prolapsed and patent Meckel's diverticulum that he had been able to discover had ended fatally, and, therefore, considerable immediate risk to life by operation was certainly warranted.—The PRESIDENT remarked that Brinton, as a result of his great experience of intussusception, had averred that almost invariably it was the proximal portion of the gut which was forced into the distal; in the case related the reverse obtained.—Mr. HOWARD MARSH asked if at the necropsy the condition of the parts suggested that the intussusception could have been reduced by manipulation after laparotomy.—Mr. GOLDING-BIRD, in reply, said he made up his mind after first seeing the case that resection would be necessary if any operation was undertaken; this view was confirmed at the necropsy.

Mr. LANGTON gave the details of a case of Osteopsathyrosis (Fragilitas Ossium) in which, after firm union of several fractures had taken place, disunion in some occurred several years afterwards. The patient, aged twenty-three when first seen in 1883, had been the subject of several so-called "spontaneous fractures" as the result of muscular action or of very slight injury. In all except one firm union had ensued, but in one fracture of the femur, after unnecessary violence on the part of a bonesetter, the fracture never became firmly united. Subsequently, two united fractures of the left femur and the right humerus disunited, and the latter eventually became the seat of a sarcomatous growth.—Mr. EDGAR WILLETT described the pathological appearances of the specimens from this case. He referred to the case of a child aged four who had sustained fractures of no less than six of the long bones. They all united readily, and the clavicle alone at present showed signs of thickening at the seat of fracture.—Mr. LUNN said that three cases of locomotor ataxy had been under his care, each with a spontaneous fracture. In one it was of the femur, in one of the tibia, and in one a Pott's fracture. These fractures in each case were unknown to the patient and were casually found by the nurse. They all united quite readily.—The PRESIDENT said that this case raised the question of the pathology of softening and fragility of bone. The sarcomatous disease could scarcely have been present at eleven years of age, when the fracture first occurred. He had seen during the last year three cases of mollities ossium, all in single women. In one under his care at the present time the patient was a young woman who was admitted with a fracture of both femora, and afterwards the humerus was fractured as the result of a slight muscular effort. The fracture of the humerus had united readily. In the other two cases there were numerous fractures of bones which did not unite, and post mortem in both sarcoma was found. He wondered if the sarcoma was a separate disease superadded to the fragility, or whether they bore any relation to each other. In locomotor ataxy it had been demonstrated that there was a great diminution of the phosphatic salts of bone—from 48 to 11 per cent.—Dr. L. BENHAM inquired if the bones were rarefied. He remarked on the frequent association of malignant disease with osteitis deformans.—Mr. LANGTON remarked, in reply, that for sarcoma to have been quiescent or latent for many years was most uncommon, and, again, the majority of the affected bones presented no malignant infiltration. The case was particularly interesting on account of disunion occurring so many years after sound repair had taken place, and of the patient being able to walk many miles in comfort on the ununited fracture.

Dr. ALTHAUS related the details of a case of Brain Tumour successfully Healed by Internal Medication. The case was that of a female aged thirty-nine, in whom unmistakable symptoms of a tumour in the right cerebral convolutions became developed in 1882. The chief signs were severe headache, cranial tenderness, and tympanitic sound on percussion, a change in her manner, drowsiness in the daytime, epileptiform convulsions, paresis of the left side of the body with increased tendon reflexes, optic neuritis, impaired memory and inability to think, and sickness and vomiting. The first symptoms had appeared after parturition, and there was a history of a severe blow on the head many years ago, but no syphilitic infection. Treatment by full doses of mercury and iodide of potassium caused rapid improvement and total disappearance of the principal symptoms in six weeks. Several relapses happened in the course of the following years, at variable intervals, and these yielded to the same treatment as readily as the first attack. The last serious relapse occurred in 1888, and a very slight one, with few symptoms, in September, 1892. Since then the patient had remained quite well and able to enjoy life. Dr. Althaus remarked upon the unusual rapidity with which the therapeutic results were produced in this case, both in the beginning and in the relapses which took place, showing a truly specific action of the drugs employed. He had in similar cases seen satisfactory results from a similar treatment, but the latter had generally been more protracted than in the present instance. He thought the tumour might have been a glioma, but as it was, fortunately for the patient, never seen and handled it was impossible to determine its nature. With regard to the diagnosis he stated that there was no other disease which would produce the whole group of symptoms which had been present, while one and all of these could be easily accounted for by the presence of a growth in the affected portion of the brain. He concluded by remarking that a case like the one related—in which such ominous symptoms as optic neuritis, epileptiform convulsions, and loss of mental power were traced to their origin and removed by acting upon the seat of the malady—not only tended to give a physician confidence in his power over disease, but also furnished a very clear reply to that therapeutic nihilism which was so frequently paraded by those who did not know how to use the remedies which were at their disposal.—Mr. LUNN said that he made the post-mortem examination of a woman aged twenty-five, in whom softening of the cerebrum on the right side anteriorly was found. This proved on microscopical examination to be a glioma. When aged ten the patient had fallen downstairs and sustained a fracture of the base of the skull, but made an uneventful recovery from that accident. In another case he had found a cerebral tumour at the seat of an old fracture. He had never heard of a glioma disappearing under the influence of drugs.—Dr. WILSON (Leytonstone) related the case of a boy aged twelve who complained of frontal headache, pain in the temporal region, and inflammation of the tympanum. Optic neuritis developed, the knee-jerks became exaggerated, ankle-clonus was present, the gait was staggering, and the lower extremities became paralysed. Under mercuric chloride and iodide of potassium he got worse, but improvement set in directly the patient was moved to the seaside. After five months he recovered and was now in perfect health.—The PRESIDENT said that the great point in the case was whether the patient was syphilitic or not; if not, the case was certainly a very remarkable one. He had seen several cases in which he had diagnosed cerebral tumour and had given mercury and iodide of potassium vigorously by routine, and in some of these cases the patients had improved so much that he had almost concluded that they might be syphilitic. They, however, had not continued to improve, and after death glioma had been found. The same experience held good with certain cases of malignant disease of the tongue and of the œsophagus. It was also to be remembered that if a case of tumour of the brain recovered under treatment one was apt to come to the conclusion from that result that it was syphilitic. He was not so sanguine as was Dr. Althaus that syphilis could be absolutely excluded in any case.—Dr. ALTHAUS, in reply, maintained that syphilis could be absolutely excluded. He thought that the original injury must have been the starting-point of the trouble.

OBSTETRICAL SOCIETY OF LONDON.

Exhibition of Specimens.—General Meeting.

A MEETING of this society was held on Nov. 6th, Dr. F. H. CHAMPNEYS, President, being in the chair. The following specimens were shown:—

Dr. CULLINGWORTH: Necrotic Change in a Small Uterine Myoma occurring in a Young Subject.

Dr. GALABIN: Œdematous Fibroid Tumour of Uterus associated with Pregnancy.

Dr. REMFRY: Tubal Gestation removed before Rupture.

Dr. LEITH NAPIER: Solid Ovarian Tumour, probably Fibromatous.

A special general meeting was then held, at which certain of the laws as revised were discussed and adopted.

LIVERPOOL MEDICAL INSTITUTION.

Suppurative Meningitis due to Chronic Otorrhœa.—Exhibition of Specimens.

A MEETING of the Pathological Section of this society was held on Nov. 7th, Mr. G. G. HAMILTON being in the chair.

Mr. C. G. LEE read notes of a case of Suppurative Meningitis due to Chronic Otorrhœa occurring in a boy aged twelve. In this case the mastoid antrum was opened and the lateral sinus exposed; pus was found in the antrum, but the sinus appeared healthy. The patient received no benefit from the operation and died some three days after it. The necropsy revealed extensive suppurative meningitis, the pus lying chiefly in the neighbourhood of the cerebellar fossæ and around the medulla. On section of the petrous bone pus was found in the labyrinth.

Mr. NEWBOLT showed a specimen of Necrosis of the Jaw from a Polar Bear aged one year. Injury at the time of capture was doubtful; the lateral incisors were carious.

Dr. BARENDT showed sections from a case of Xanthelasma which was associated with jaundice.

Digitized by Google

Mr. THOMAS exhibited sections from Mr. Parker's case of Coccygeal Tumour; also specimen and sections of a Tumour of the Leg. The primary growth was removed from the skin of the leg of a man aged twenty-two. The growth, which had apparently begun between the epithelium and the corium, consisted of large epithelial cells arranged in long alveoli, and was not pigmented. The secondary growths in the groin had a similar structure, but were deeply melanotic. He considered the growth to be a carcinoma arising from the abnormal cells of a mole.

Mr. PAUL showed a beautiful series of lantern slides illustrating the Structure of Villous, Adenomatous, and Carcinomatous Tumours of the Rectum, and a further series illustrating his view as to the Nature of Axillary Breast Tumours (four cases).

Professor BOYCE and Dr. ALEXANDER showed a specimen of Dermatolysis removed by Dr. Alexander from a young woman. She had been under observation for very many years, and it was probable that the tumour was congenital or started in early childhood. It had steadily increased in size and at the time of operation formed huge pendulous folds from the side of the neck and chest. Microscopic examination showed that the tumour consisted of a neoplasis of the cutis vera, which in some places reached an inch in thickness. The tissue was composed of delicate but firm fibrous tissue containing very numerous thin-walled vascular sinuses. There was very marked atrophy of the epithelium and of the sebaceous and hair follicles. Owing to the overgrowth of the corium the sweat glands were far removed from the skin, but preserved their relationship to the sub-areolar tissue, which was normal; the glands were undergoing degeneration. This case of overgrowth of the corium was compared with the other forms of elephantiasis and molluscum, where the neoplasis commenced as a perineural (elephantiasis neuromatosa), a perivascular, or a perilymphatic growth, or consisted in overgrowth of the fibrous bundles in the areolar tissue. It was an instance of the limitation of growth to a special tissue system.—Dr. ALEXANDER, Mr. HAMILTON, Mr. MURRAY, Mr. PARKER, Mr. PAUL, and Professor BOYCE took part in the disussion which followed.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Hemiplegia produced by Embolism of the Left Middle Cerebral Artery.

A MEETING of this society was held on Nov. 7th, the President, Dr. PORTER, being in the chair.

Dr. CUFF showed a young man the subject of Congenital Syphilis with Congenital Malformation of both Radii. In each arm the diaphysis of the radius was absent. The epiphysis of the head could be easily felt on both sides below the external condyles. The epiphysis of the carpal end, small in size, could be distinctly made out on the left side; on the right side an indistinct bony mass abutting on the shaft of the ulna probably represented the carpal epiphysis dislocated towards the ulna. The position of the hands was peculiar, each hand being dislocated towards the radial side and displaced upwards.

Dr. SINCLAIR WHITE showed a successful case of Estlander's Operation.

Dr. ARTHUR HALL showed a case of Lupus Vulgaris which had been treated by tuberculin injections with satisfactory results.

Mr. PYE-SMITH showed a large Carcinomatous Tumour of the Right Ovary which he had recently removed by ovariotomy from a woman aged forty-seven. There were extensive adhesions to the bowels and uterus, but no secondary infiltrations or deposits. The left ovary was free from disease. The patient survived the operation thirty hours.

Mr. PYE-SMITH also showed a Right Upper Canine Tooth which had been driven up by a kick at football two years before and embedded in the anterior wall of the maxillary antrum. A year after the injury a sinus formed in the cheek and had remained open ever since. Recently the lad consulted Mr. West Jones, who discovered the tooth and sent him to the Royal Hospital. The lingual aspect of the tooth was anterior; the fang, which was not quite completely formed, projected upwards.

Dr. PORTER showed an Aneurysm of the Ascending Aorta which had pressed upon the right bronchus. There was a curious defective condition of the cartilaginous rings in both bronchi (congenital).

Dr. CUFF read the notes of a case of Hemiplegia produced by Embolism of the Left Middle Cerebral Artery. At the necropsy there were found recent vegetations on the aortic and mitral valves, general meningitis, an embolus blocking the left middle cerebral artery at its commencement, and consolidation of the apex of the right lung.

The PRESIDENT, Dr. KEELING, Mr. KNIGHT, Mr. PYE SMITH, Dr. SAMSON MATHEWS, Mr. GARRARD, Dr. SINCLAIR WHITE, Dr. BURGESS, Dr. WILKINSON, Dr. ARTHUR HOLT, and Dr. CUFF made remarks on the cases and specimens.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Successful Case of Porro's Operation.—Papilloma of the Bladder, complicated with Hæmoglobinuria.—Vesiculo-bullous Dermatitis.—The Utility of testing for Indican in the Urine.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 1st, Mr. MAYO ROBSON, President, being in the chair.

Mr. MOYNIHAN read a paper on a Successful Case of Porro's Operation. The patient, a dwarf forty-nine inches in height, had been in labour for twelve hours. Müller's modification of Porro's original procedure was adopted. Both patients did well.—Mr. BROWN mentioned three cases of Cæsarean section which he had performed, and said that in considering the failure and success resulting from all operations of this kind it must be borne in mind that the cases usually occur in poor people living in insanitary conditions. He thought Porro's operation infinitely preferable to craniotomy or Cæsarean section.—Dr. KILNER CLARKE had performed Porro's operation twice, and laid stress on the importance of after-nursing.—The PRESIDENT considered craniotomy unjustifiable except where the child was already dead. Porro's operation was infinitely simpler, and had the great advantage of preventing a future pregnancy.—Mr. MOYNIHAN, in replying, said that the condition of some osteomalacic patients had improved after the operation.

Mr. ATKINSON read a short paper on a case of a Papilloma of the Bladder complicated with Hæmoglobinuria. A man aged fifty-seven years began early in the present year to pass blood-coloured urine at intervals. The attacks, which at first occurred about two or three weeks apart, were painless, and not preceded by nausea, chill, or any malaise; they came on suddenly and departed gradually. The urine was dark and porter-like, even turbid at times, with chocolate-coloured sediment. After two or three days it became clear and normal. Mr. Atkinson first saw it in April and found much albumin, but no blood discs. Paroxysms occurred at decreasing intervals up to June. In July the patient passed bloody urine, the urethra being at times blocked with clot. In August Mr. Atkinson, suspecting stone, sounded with a negative result, but on passing the catheter later withdrew a shred of villous-like tissue in the eye of the instrument, brisk hæmorrhage following. On Aug. 23rd the bladder was explored through a suprapubic incision, and a fimbriated papilloma with broadish base attached to, and about, the trigone was found, and removed with forceps and finger-nail. The patient made a good recovery and was out on the eighteenth day, and is now perfectly well. It should be remarked that five years ago he passed a small stone, and that he is the subject of syphilitic taint of many years back, now indicated by occasional patches of psoriasis.—The PRESIDENT wished to know whether there was any return of hæmoglobinuria.—Mr. ATKINSON replied in the negative.—Dr. CHURTON mentioned a case of hæmoglobinuria complicated by syphilis which was improved by calomel.—Dr. BARRS refused to believe that there was any connexion between syphilis and hæmoglobinuria.—Mr. LAWFORD KNAGGS related a case of a child having syphilitic periostitis, interstitial keratitis, and its knees full of fluid. Hæmoglobinuria appeared five years later.

Dr. BARRS reported the case of a girl aged seventeen years, who, after three separate attacks of dropsy due to chronic Bright's disease, developed an almost universal Vesiculo-bullous Dermatitis, and ultimately died in coma. At the necropsy the kidneys showed advanced parenchymatous nephritis. The eruption appeared three weeks before death

Digitized by Google

and was accompanied by intense pains in the feet, which were most affected. The plantar and dorsal surfaces of the feet were covered by one enormous blister, the fluid contents of which had an offensive odour. Dr. Barrs believed that the bullous form of uræmic dermatitis had not previously been recorded in this country.—Mr. SOLLY (Harrogate) thought that extensive skin diseases might cause damage to the kidneys; and, on the other hand, that kidney disease gave rise to skin diseases, mainly of the pruritic character.—Dr. CHURTON had for years looked in vain for skin diseases in uræmic cases.—In his reply, Dr. BARRS joined issue with Mr. Solly on both his statements.

Dr. CHURTON read a paper on the Utility of Testing for Indican in the Urine. Indican in the urine meant that the putrefactive product was circulating in the blood and tissues and poisoning them either by itself or by its associated toxines. It was easier to test for indican than to inquire into the probability of this toxæmia by questions as to constipation or diarrhœa, colon flatulence, &c. Dr. Klein had found that indol is formed by the bacillus coli in meat broth at 37° C., and that a variety of this bacillus produced a toxine extremely fatal to guinea-pigs. It had also been shown that some pathogenic microbes can form their poisons only when products of putrefaction are present. It was not correct to say that disease of any kind involving the intestines is attended by indicanuria. Dr. Churton had demonstrated its absence in some cases of prolonged constipation, typhoid fever, and strangulated hernia. He doubted the existence of persistent, even slight, indicanuria in perfectly healthy persons. As examples of the utility of finding indican in the urine he briefly described cases of delirium with convulsions, cholera nostras with collapse, delirium with spasm of certain muscles, supposed typhoid fever (proved by treatment based upon the discovery of excessive indicanuria to be merely fæcal toxæmia), diarrhœa, probably from subacute colitis, and gout—in all of which, as in many others, the indicanuria entirely governed the treatment—namely, removal of the contents of the colon and the use of antiseptics. Washing out the colon (very cautiously if ulceration was suspected), calomel in small doses, salol, a milk diet variously modified, and stimulants if required were the means usually employed. The colon was washed out even when (non-inflammatory) diarrhœa was a leading symptom, as in the cases of English cholera, for instance.—Dr. TREVELYAN spoke of the importance of examination of the urine for various poisons. Typhoid fever bacilli had been found in the urine. Cases of tetany—recorded in association with gastric dilatation—and many cases of migraine so often seemingly due to stomach derangements might be caused by poisons absorbed.

The following patients and specimens were shown:—

Dr. CHURTON: Blood from patients with Typhoid Fever showing absence of Leucocytes.

Dr. DE BURGH BIRCH: A Simple Form of Microtome.

Dr. ADOLPH BRONNER: Case illustrating Mr. Victor Horsley's Method of Operating in cases of Extensive Disease of the Mastoid Process.

Mr. W. H. BROWN: Two cases of Dislocation of the Astragalus, one with fracture.

Dr. T. WARDROP GRIFFITH: Specimens from two cases of Hæmorrhage into the Pons Varolii. In both cases there were very extensive kidney disease and much cardiac hypertrophy. In one case the vessels throughout the body were atheromatous, while in the other most careful examination failed to reveal any naked-eye disease of the vessels.

Mr. LAWFORD KNAGGS: Case of Double Glaucoma in a Young Man following Influenza.

Mr. NUNNELEY: Brain and Temporal Bone from a case of Middle-ear Disease with Lateral Sinus Phlebitis.

Mr. LITTLEWOOD: (1) Calculus (weighing four ounces) with Kidney removed by Abdominal Nephrectomy; (2) case of Dupuytren's Contraction treated by dissecting out the Contracting Band; and (3) large Bursa Patellæ.

Mr. SECKER WALKER: (1) Specimens from a case of Middle-ear Disease complicated by Cerebellar Abscess and Phlebitis of Lateral Sinus; and (2) a Temporal Bone from a patient operated upon two years ago for extensive Disease of the Mastoid Process. The whole of the process had been hollowed out by ulceration, and, having been scraped and cleaned, a flap of skin was dissected from the back of the ear and turned into the cavity and pressed by a dressing against the bony floor. Ultimately the whole cavity became lined with epithelium continuous with the open air through the mastoid opening.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Treatment and Causes of Cold in the Head.

A MEETING of this society was held on Nov. 5th, Dr. ADOLPH BRONNER, the President, being in the chair.

Dr. J. H. CRAWFORD gave a Microscopical Demonstration of Malignant Tumours, the specimens illustrating not only the different varieties of sarcomata and of carcinomata, but also the various stages of malignancy of tumours.

Dr. SHIACH showed a patient suffering from Melanotic Sarcoma affecting the skin of the abdomen below the umbilicus, the inguinal glands being also enlarged. The patient was a man aged fifty with no family history of new growth and with no signs of secondary deposits elsewhere.—Mr. HORROCKS discussed the question of operation, and was of opinion that it would not be of any good in this case.

Dr. H. BRONNER showed a specimen from a case of Kidney Disease due to Double Calculus. The patient was a man aged fifty-eight, of steady habits, who worked till five days before admission into the infirmary. He complained of diarrhœa, vomiting, and loss of flesh. The urine was of sp. gr. 1009, and contained a small quantity of albumin, but no casts; the quantity in twenty-four hours was 72 ounces. No signs of malignant disease were found. The symptoms whilst under observation were melæna, purpuric eruption on arms, legs, and body, and dyspnœa. On post-mortem examination calculi were found in each kidney; the left ventricle of the heart was hypertrophied and the aorta thickened.—The case was discussed by Dr. A. BRONNER, Dr. RABAGLIATI, and Dr. MAJOR.

Dr. RABAGLIATI showed a specimen of an Ovarian Tumour which he had recently removed; there were no adhesions found at the operation, and the patient made a good recovery. The question as to the side from which the tumour springs in these cases was discussed.—Dr. RABAGLIATI also showed a Stomach with Two Perforations. On abdominal section he had experienced great difficulty in stitching up a perforation of the posterior wall of the stomach, the one on the anterior wall not having been noticed at the time of the operation and only discovered post mortem.—Mr. HANDCOCK, Dr. CRAWFORD, Mr. HORROCKS, and Dr. H. J. CAMPBELL made remarks, and Dr. RABAGLIATI replied.

Dr. BAMPTON read a paper on the Treatment and Causes of Cold in the Head, of Influenzal Origin. The usual methods of clothing the head and the feet were criticised and suggestions made, especially as regards the covering of the head. The treatment which he had found advantageous for the symptoms met with in influenza was given, stress being laid on rest in bed, warmth, and stimulation.—Dr. MAJOR, Dr. RABAGLIATI, Dr. GOYDER, Mr. FARRER, and Dr. S. LODGE, jun., discussed the paper, and Dr. BAMPTON replied.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

President's Address.—Exhibition of Cases and Specimens.

THE first meeting of the seventy-fifth session was held on Nov. 6th, Dr. CRAIG, Vice-President, being in the chair.

Dr. GIBSON read a letter from Dr. CLOUSTON, the President, in which he regretted his unavoidable absence through illness. Dr. Gibson then read the President's Valedictory Address. No member of the Medico-Chirurgical Society now living, Dr. Clouston said, could, he believed, take the President's chair without a deep sense of his inferiority in mind and attainments to many of the men who had sat there before him. The society had been presided over in the past, not only by great physicians and surgeons, but by great men. Brain power seemed to come to mankind in waves, and surely as students of heredity we were entitled to anticipate that the race which bred those great men in the past would again procreate men like unto the former generation. Physic was not alone in the trough of the wave. Politics, literature, journalism, law, and divinity were alike crying out for leadership. But was there no compensation for this state of matters? If no one man made extraordinary advances, were there not ten making moderate acts of progress, and the sum total of our work might be comparable in its usefulness to mankind to that

Digitized by Google

of the great inventors and discoverers? During the last two years the society had been doing good work, and medicine and surgery had on the whole been the better for the meetings. The muster-roll of the society reached now 360 members. What a vast mine of experience did this imply. He thought enough was not made out of cases in ordinary practice for the benefit of the society. He sketched what to his mind was an ideal medico-chirurgical society, where no man should prose and no man go into unnecessary detail, every meeting being so interesting and instructive that members should look upon it as a hardship to be kept away by necessary business. The discussions during the past sessions on Cranial Surgery and on Cardiac Therapeutics would serve as landmarks to show exactly the Edinburgh practice and theory on those questions at the time. Professor Fraser's communication on Immunity from Snake Poisoning was no doubt the most original, pregnant, and far-reaching discovery that had been communicated to them, and the society might well congratulate him, as well as feel proud that the tradition of the profession was still as strong as ever, that any man who had made a great discovery or had arrived at the result of any important investigation in Edinburgh came at once to the Medico-Chirurgical Society to announce it. Dr. Clouston pointed out that he was the third specialist who had sat in the President's chair, and, as a specialist, he naturally regarded most questions from his own standpoint. Repeatedly in the discussions questions had struck him as a specialist in the nervous system. From the chair he looked on all the proceedings with a mind filled with one idea. Every case, every opinion expressed, was observed by him from the cortical and mental standpoint. The brain cortex was the Pharaoh whose throne towered above all else, whose will was law, who represented everything, in whom all his subjects centred and ended. He dwelt eloquently and at considerable length on the preponderating influence of the nervous system in disease. During the President's term of office the society had lost several members by death. Three of these were high types of the best qualities of the profession. No more marked individuality than Dr. Thomas Keith ever walked the streets of Edinburgh or contributed, as he did, so brilliantly to the work of the society. How well they all could picture his keen, nervous face, the "far-away" look in his honest eyes, the head set forward, the anxious attitude, and the deep, earnest voice. Dr. Brakenridge had passed away too — a powerful clinical teacher, a high-minded, earnest man, a subtle, accurate thinker, and a loyal friend. Dr. Thomas A. G. Balfour had been a frequent attendant at the meetings of the society. He was a man beloved by his many patients, and, beyond a doubt, exerted a powerful influence for good during his long and useful life. If family medical attendants were all such as he was how well should the profession stand with the public.—On the motion of Dr. JOSEPH BELL, seconded by Dr. JAMES CARMICHAEL, a hearty vote of thanks was accorded to the President for his address.

Dr. STEWART STIRLING showed a case of Erythema Multiforme (Papulatum). When first seen the spots, which nearly covered the trunk, had a raised erythematous appearance, the redness disappearing on pressure. After treatment with tar and calamine lotion lichen papules appeared combined with the erythema. The eruption now consisted of numerous irregular spots and patches over the trunk, of a deep-red colour. There was an entire absence of scales and itching. No case exactly similar had been reported. Hutchinson had described cases of a somewhat similar kind, but there were points of distinct difference.

Dr. STIRLING also showed a case of Lupus Erythematosus of the Scalp.

Dr. NORMAN WALKER showed a boy suffering from Erythema Multiforme. He and his two elder sisters had the rash, which began as small round spots spreading in a circinate manner over the forearm and back of hand. A spot had been excised and showed the well-known features of great cell proliferation around the vessels. Quinine did good when exhibited in very large doses.

Dr. JAMES CARMICHAEL showed a specimen of Double Intussusception from a child aged nine years who was admitted to the Royal Hospital for Sick Children suffering from diarrhœa and extreme asthenia of six weeks' standing. There was an enormous polapse of the rectum. There was no obstruction of the bowels or distension. He sank and died. Post mortem the ileum was found invaginated into the cæcum, and the cæcum into the transverse colon. The mass occupied the left hypochondrium. There was no obstruction. Probably the intussusception had taken place shortly before death.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Abdominal Hysterectomy.—Anencephalic Fœtus.

THE first meeting of this society was held in the Faculty Hall on Oct. 23rd, the Honorary President,. Sir JOHN WILLIAMS, Bart. (London), being in the chair.

The PRESIDENT made a suitable reference to the death of Dr. Thomas Keith, who was one of the honorary Fellows of the society, and proposed that an expression of their regret at the loss the profession had sustained, and of their sympathy with his widow and family, should be entered in the minutes of the society, and that an excerpt from the minutes should be sent to Mrs. Keith. The President reported, as supplementary to his address on the occurrence of Tetanus Neonatorum in the island of St. Kilda,[1] that antiseptic precautions are now being observed in the treatment of the umbilical cord, and that the two children born in the island since he read his paper last year have escaped an attack and are still living.

Professor MURDOCH CAMERON read notes on a successful case of Abdominal Hysterectomy for Myomata of the Uterus complicated with Pregnancy of five months' duration. The patient was thirty-six years of age and had not previously been pregnant. A small tumour about the size of a hen's egg had been observed on the left side about eight years ago. This gave no trouble, and remained stationary till she became pregnant last February. When she was first seen on July 16th the abdominal distension suggested a pregnancy at full time. On account of severe pressure symptoms abdominal section was performed on July 22nd, and the whole of the pelvis and left iliac and lumbar regions were found to be occupied by the tumour masses, the uterus being displaced to the right side. It was found to be necessary to remove the whole of the uterus with the tumour. The parts removed weighed 27 lb. Recovery was uninterrupted.

Dr. MALCOLM BLACK showed an Anencephalic Fœtus.

[1] See Glasgow Medical Journal for March, 1895.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next examination for the medical certificate will be held in December. Those who are competing for the Bronze Medal and Prize must send in their essays to the president, Dr. Nicolson, Broadmoor Criminal Asylum, on or before May 30th, 1896. Particulars on both subjects can be obtained from the registrar, Dr. Spence, Burntwood Asylum, Lichfield.

INSANITARY BOARD SCHOOLS AT PORTSMOUTH.—The Portsmouth School Board has now quite completed, at a cost of £2,700, what is practically an entirely new system of drainage. Two or three cases of sickness in April last led to inquiries which showed a most dangerous state of affairs, and the medical officer of health having had his attention drawn to the drains at the schools in the particular district in which the sickness occurred, notice was served on the board to put them right. When the ground was opened it was found that many pipes were broken or that the joints had entirely perished. The whole system was taken up and replaced with more modern improvements, proper inspection chambers and ventilating shafts being fixed. The matter did not end here. All the other schools in the town were visited by the medical officer, and just before the long holidays the board had notice to put the whole of the drains in complete and proper order. In some of the older schools the sanitary arrangements were found to be very defective. They were provided under the supervision of the sanitary authority of a former day, but the use of clay joints and the frequent absence of means of inspection and ventilation left the arrangements far behind modern requirements. Broken pipes abounded, probably as a result of the drains having to be uncovered in order that they might be inspected. The ratepayers object to a big bill in excess of the usual half-yearly estimate, but, considering the especial danger from ill-ventilated drains in such a position, it is far cheaper than an epidemic of sickness among the poorer children would probably have been.

Reviews and Notices of Books.

The Deformities of the Human Foot, with their Treatment. By W. J. WALSHAM, M.B., C.M.Aberd., F.R.C.S.Eng., Senior Assistant Surgeon, Surgeon in Charge of the Orthopædic Department, and Lecturer in Anatomy, St. Bartholomew's Hospital; and WILLIAM KENT HUGHES, M.B.Lond., M.B.Melb., M.R.C.S.Eng., L.R.C.P.Lond., Orthopædic Surgeon, St. Vincent's Hospital, Melbourne; Assistant Surgeon, Children's Hospital, Melbourne; Surgical Tutor, Trinity College, Melbourne; sometime Clinical Assistant in the Orthopædic Department, St. Bartholomew's Hospital, &c. London: Baillière, Tindall, and Cox. 1895. Price 18*s.*

FROM the preface to this work we learn that it was written at the request of the students of St. Bartholomew's Hospital and is chiefly founded on the demonstrations given in the Orthopædic Department on cases under treatment. Of course, in order to make the account sufficiently full and complete the authors have gone more thoroughly into anatomical and pathological points as well as the treatment of severe cases of deformity than can ever be the case with experience founded simply on the treatment of out-patients. The first chapter is devoted to the Anatomy and Mechanism of the Normal Foot, and these are considered very fully by the authors. The various forms of club-foot are then described and discussed, and afterwards deformities of the toes, such as hallux valgus, varus, and dolorosus (or rigidus), hammer-toe, and deformities of the smaller toes are dealt with. The largest amount of attention is given, as would be expected, to talipes equino-varus, especially the variety of congenital origin. Its pathological anatomy is fully treated of; then follows the treatment (*a*) before the child has walked, and (*b*) in the child who has walked, and in the adult, under the various heads of: (1) manipulative treatment; (2) mechanical treatment; and (3) operative treatment. In the section devoted to mechanical treatment many forms of surgical apparatus are described, and we fear the student will find it difficult to make a selection without more definite instructions than are given. This part of the book is, however, valuable for reference for those engaged in hospital work. The authors speak very cautiously about the usefulness of Phelps's operation, but although there is much in the objections to it which they put forward we think that the experience of others is decidedly in favour of it for severe cases of deformity. With careful after-treatment most satisfactory results have been shown. In the treatment of acquired flatfoot the authors speak very strongly in favour of the "tip-toe movements," as recommended by Mr. Ellis, which are undoubtedly curative in the milder cases. Throughout the work much prominence is given to the use of plaster-of-Paris bandages, and in the severer forms of flatfoot the bandage is applied after wrenching the foot into position. This method proved so successful that it was only considered necessary to perform one operation involving a section of the bone in about 1500 cases. The authors say: "But our contention is, and we hold that this contention is fully justified by the large experience we have had in the treatment of several grades of the affection, that although the outward contour of the foot and the extreme rigidity may lead us to infer that advanced bone changes have occurred, these may not exist. Under an anæsthetic the deformity may be found to be due to little more than displacement," &c. This quite agrees with the general experience of surgeons in other London hospitals. We think the authors attach too much importance to the use of apparatus after operation for the holding down of the toes in talipes cavus; in the same way apparatus applied for the correction of hallux valgus and hammer-toe usually fails to effect any benefit, and in both these conditions, when they are severe enough to make the patient apply for relief, it is usually best to perform some operation. As regards the etiology of the hammer-toe no sufficient evidence is given that the condition depends on a primary contraction of ligaments; we grant that they are contracted, but hold that this is secondary to displacement of the phalanx. The illustration of a dissected toe conveys no impression of the real pathological condition; the changes in the head of the bone, which prove such an impediment to the success of methods of treatment other than excision of the head, are not shown, nor are they clearly pointed out in the text. The book is well and clearly printed, there is a sufficient index, and the illustations are very numerous and usually clear and adequate. Some might, however, be changed with advantage in another edition, and we do not like to see the name of the instrument-maker so often in the illustrations of the more common apparatus.

Altogether the book places before us the modern methods of treatment and the theories of causation, as well as the results of investigations into the pathology, of these deformities in a manner which renders it a valuable addition to the surgeon's library.

Gunshot Injuries: their History, Characteristic Features, Complications, and General Treatment, with Statistics concerning them as they have been met with in Warfare. By Surgeon-General Sir T. LONGMORE, C.B., Q.H.S., F.R.C.S., late Professor of Military Surgery in the Army Medical School, Officer of the Legion of Honour, Associate of the Society of Surgery of Paris, Corresponding Member of the Academy of Medicine of France, &c. Second edition. Illustrated by twenty-eight woodcuts. London and New York: Longmans, Green, and Co. 1895. Price 31*s.* 6*d.*

IT is seventeen years since the first edition of this work appeared, and its author lived to see the publication of a second edition, on the preparation of which he had spared neither time nor trouble in his conscientious endeavours to incorporate all the information which he could gather together and subject to his careful consideration, analysis, and arrangement. Military surgery and military surgeons are to be congratulated on the fact that the author of this elaborate treatise was enabled before his lamented death in the present year to witness and pass in review all the remarkable changes that have been brought about in modern warfare, and especially in the firearms and projectiles of the leading armies of the world. It enabled him in a measure to calculate and forecast the probable effects these would have upon wounds and injuries in the wars of the future. There are many people who still cling to the hope that international disputes will ere long be settled by other methods, but they can find no ground, unhappily, for a realisation of their hopes in the records of modern history and in the events of which they hear and read. It must be confessed that wherever we look in the map of the world as it exists at the present time the picture is a disquieting one and gives no assured prospect of peace. Setting aside the recorded observations and experiences of pre-Crimean times, what a vast number of observations have been accumulated since then and within the lifetime of the late Sir Thomas Longmore—during the Crimea, the Indian Mutiny, the wars with China, Abyssinia, Ashanti, Afghanistan, and Egypt—in which this country and India were engaged—besides the numerous wars in which other countries have taken part, some of which have been on a vast scale and attended by stupendous results. This treatise consists of eleven sections and an appendix, and embraces such subjects as gunshot injuries and the means by which

Digitized by Google

they are produced, the causes which influence their nature, characters, progress, and ultimate issues, their features and distinguishing signs, and the primary symptoms and complications, with their ulterior consequences and disabling effects, their treatment in field practice, and the administrative arrangements in time of war, with the statistical results and ratios of casualties in different wars. Notwithstanding the painstaking care and labour which the author has bestowed upon his work in order to bring it up to the very latest dates, and the fact that we seem to have about reached the limits of deadly effectiveness in our modern rifles, there is, and there can be, no finality about our knowledge of a subject on which the inventive faculties and ingenuity of man are constantly being exercised, while the nature of the propelling forces and of the weapons and the dimensions, weight, velocity, and range of the projectiles employed in war are consequently being changed in accordance with our progress in inventive and experimental discovery and skill. Antiseptic surgery and Listerism have, moreover, profoundly affected the surgery of war and our practical aims in this respect. Still, the objects to be attained and the principles and indications on which the action of a medical service in modern war must always be based will probably remain much the same that they are now.

It is impossible to review a work of this size and importance within a reasonable space, and we do not think that there is any occasion for doing so in regard to the second edition of a treatise with which all who are interested in the subject are probably already well acquainted. The revolution, moreover, which has taken place of late years in the modern rifle has introduced changes which have excited universal attention in connexion with the surgery of war. There is no work with which we are acquainted that gives such an amount of information on the subject generally as that about which we have been writing.

LIBRARY TABLE.

Archives de Physiologie Normale et Pathologique. Fondées par Brown-Séquard. Publiées par MM. Bouchard, Chauveaux, et Marey. No. 4. October, 1895. Paris: G. Masson.—The more important papers published in this number are—(1) M. G. Gérard on the Existence of Arterio-venous Anastomosis; (2) on the Morphological and Pathogenic Varieties of the Agent producing Surgical Purulent Infection, by MM. S. Arloing and E. Chantre, with two plates; (3) an Apparatus for Measuring Respiratory Exchanges, by M. F. Laulanié; (4) Researches on the Amylolytic Ferment of the Blood (Hæmodiastase), by M. A. Tcherevkoff; (5) Variation of the Gaseous Exchanges of a Muscle, removed from the Body, for some days after its Extraction, by M. J. Tissot; (6) on the Antitoxic Action of Organs, by M. J. E. Abelous; (7) Introduction to the Study of the Disturbances of the Temperature under the Influence of Bacterial Toxines, by MM. S. Arloing and F. Laulanié; (8) on Experimental Hepatic Lesions caused by Diphtheritic Toxine, by MM. J. Courmont, M. Doyon, and M. Paviot; (9) Experimental Study of the Action of Sparteine and Oxysparteine in Chloroform Anæsthesia, by MM. P. Langlois and G. Maurange; (10) on the Saline Digestion of Gelatine, by MM. A. Dastre and N. Floresco; (11) the Influence of Variations of the Intra-hepatic Lymphatic Circulation on the Anti-coagulating Action of Peptone, by MM. E. Gley and v. Pachon; (12) Researches on the Cerebral Pulse in its Relation with the Attitudes of the Body, with Respiration, and with Psychical Acts, by MM. Binet and P. Sollier (interesting); (13) on the Variation of the Volume of the Limbs in connexion with the Respiration, by M. E. Wertheimer; (14) Fresh Researches on the Vaso-constrictor Action on the Pulmonary Vessels of the Sympathetic Trunk, by M. Ch. A. François-Franck; (15) Autopsy and Death of an Agastric Cat, by MM. J. Carvallo and v. Pachon; (16) on the Toxicity of the Serum of the Blood in Dogs subjected to Thyroidectomy; (17) on Trophic Troubles accompanying Syringomyelia, by MM. J. Dejérine and Ch. Mirallié; and (18) on the Poisoned Arrows of French Soudan, by MM. Ferré and Busquet.

The Seventy-fifth Annual Report of the Dundee Royal Asylum. June, 1895.—The directors report that the institution is now in a prosperous condition. This is satisfactory, and much credit is due to the able and conscientious management of Dr. Rorie, considering that only quite recently the asylum was greatly crippled financially. The Mansion House of Gray, in the immediate neighbourhood, has been obtained on lease and is now occupied by private patients, thus releasing part of the main building for the accommodation of the increasing numbers of pauper insane. There were 163 admissions during the year, 51 recoveries, and 55 deaths; the total number under treatment was 579. It may be noted that one of the three resident clinical assistants was a young lady.

Dental Materia Medica and Therapeutic. By JAMES STOCKEN. Fourth edition, revised by LESLIE M. STOCKEN and J. O. BUTCHER. London: H. K. Lewis, 136, Gower-street, W.C. 1895.—There are a fair number of drugs in general use in the practice of dental surgery the descriptions of which are not included in the ordinary text books on materia medica. For this reason a small work dealing with these special drugs is really called for. It is intended that this book should fill that gap, but unfortunately it can hardly be said to do so at all adequately. Many drugs of value are not included: for instance, we find no account of beta-napthol, gallic acid, trichloracetic acid, peroxide of soda, pyrogene, and oxide of zinc. The subject-matter is divided under three headings, of which the first deals with Materia Medica, Pharmacology, and Therapeutics, the second is devoted to a description of the various drugs, while the last contains a therapeutic index of diseases, drugs, and prescriptions. Speaking generally, the description of many important drugs is far too meagre. Useful remedies like tincture and liniment of iodine are mentioned only by name, and no account is given of their strengths and the modes of their preparation.

JOURNALS AND REVIEWS.

Archiv für Verdauungs-Krankheiten (Archives of Diseases of Digestive Organs). Berlin: S. Karger. London: Williams and Norgate. Annual subscription, 16*s*.—This journal, of which the first part is before us, is edited by Dr. J. Boas of Berlin, and is to appear quarterly. The contents of this first number may be taken to indicate its scope. The editor opens with an article on the Aims and Methods of the Pathology of Digestion; Professor O. Rosenbach of Breslau follows with a paper on Hepatitis Simplex, with remarks on Abdominal Plethoric and Hæmorrhoidal Conditions. Professor C. von Noorden of Frankfort writes upon the Therapeutical Importance of Researches in Metabolism; and Dr. Reichmann of Warsaw contributes results of his Experimental Researches upon the Direct Influence of Sodium Bicarbonate on the Secretion of Gastric Juice. A review of current literature for the second *semestre*, 1894, under the several headings of—(1) Œsophagus; (2) Stomach; (3) Intestine; (4) Liver; (5) Spleen; (6) Pancreas; (7) Mesentery, in Germany contributed by Dr. P. Cohnheim, and of similar writings in Russia and Poland contributed by Dr. Grundzach, in Hungary by Dr. S. Pollack, in Scandinavia by Dr. L. Wolff, and in Denmark by Dr. C. Jürgensen—followed by a bibliographical summary of such literature in all

Digitized by Google

countries for the first quarter of 1895, compiled by Dr. Roth, librarian of the University Library at Halle, form a prominent feature of the *Archiv*. Reviews of Dr. Lennander's monograph on Appendicitis, and of Dr. A. Pick's Lectures on Diseases of the Stomach and Intestines, complete the number.

The Popular Science Monthly.—By far the most interesting paper in the October number of this journal is Professor Michael Foster's article on Huxley. Mr. Herbert Spencer continues his papers on Professional Institutions, or rather under this heading he continues to show how all education was at first coexistent with the sacred ministry of whatever nation or religion he treats of.

The Medical Magazine.—Mr. David Wallace contributes an interesting paper upon Cystoscopy to the October number. He mentions the use of a Higginson syringe for introducing the solution, but we prefer a simple tube and funnel, for by this means the amount of pressure can be more easily gauged. Mr. Nelson Hardy's paper on the Doctor's Holiday is amusing. He went to D——shire to take another man's work and was astonished to find that the country aristocracy, instead of being bold, bad baronets, were actually humane. The Ladies Rose and Cicely, for instance, looked after the parish nurse, and the local baronet sent his phthisical footman to a convalescent home. So far have we advanced since the days of Lady Southdown and Podger's pills. The November number has two interesting papers by Dr. Withington—the one about the medical man who was sent by Pope Alexander III. as *Legatus a latere* to Prester John; the other a delightful paper upon Strange Medicines, from which we extract the following, commending it to sundry ecclesiastical authorities: "There is nothing better for that dangerous disease, lethargy, than to put fleas in the patient's ears, as I have seen done with happy success to my lord the Earl of Shrewsbury in England."

Bristol Medico-Chirurgical Journal. September. — The quarterly organ of the Bristol Medico-Chirurgical Society has among other articles Mr. H. P. Symonds's presidential address at the annual meeting of the Oxfordshire Branch of the British Medical Association, on the Advances in Surgery during the last Twenty-five Years. Dr. Fawcett contributes a paper on a Method of Localising the Foramina at the Base of the Skull, which we recommend all those struggling with their "bones" to read and digest. There is a paper by Dr. Michell Clarke on the Diagnosis of Cancer and Simple Dilatation of the Stomach, and Remarks on the Administration of Ether, founded on 400 cases, by Mr. Freeman.

The Medical Chronicle.—This, the medical magazine of the Owens College, Manchester, contains amongst others Mr. Treves's paper on the Surgical Aspect of Tuberculosis, published in our issue of Oct. 26th. There is an excellent article on Bakehouses by Dr. Niven, the medical officer of health of Manchester.

Dublin Journal of Medical Science.—The original communications to this quarterly comprise a paper on Internal Strangulation by Mr. W. Thomson, one on Osteotomy for aggravated Equino-varus by Mr. R. L. Swan, and an interesting paper on Old Herbal Remedies by Dr. Purdon.

The *Humanitarian* for November contains two articles by medical men, one on Cycling for Ladies, which does not add to our medical knowledge on the subject, and one, a mere note, on Drink and Insanity, which exaggerates, to our mind, the evil connexion between the two. With Mr. F. H. Walmsley's opinion that it should be a question for consideration whether the law should not be amended so that such (habitual) inebriates, instead of being committed to prison for short terms, should be detained and treated for lengthened periods in special institutions, we are in full accord; but when he says that "half the misery ar wretchedness of human life . . . is the outcome of a abnormal state of mind and morals produced by drink w believe that he overstates his excellent case.

The *Practitioner* for November contains several interestin papers, among which we may mention for special attentio an historical note on Conical Cornea by Mr. Anderso Critchett and a communication on the subject of Deaf Mutism by Mr. Bertram Thornton. Mr. Thornton say definitely, in answer to a question that is still under som discussion: "It is almost equally certain that con sanguineous marriages are responsible for a considerabl proportion of children who are born deaf." The othe "certainty" to which this is equivalent is the influence o heredity.

The *Strand Magazine* for November contains a story ir the second series of "The Diary of a Doctor," which is in this respect better than many of its predecessors that its medical element has nothing to do with the interests. The part played by the medical man is not scientific but accidental, and medical treatment or diagnosis forms no essential of the narrative. A paper on the Signature of Napoleon is a real argument for seeing something sound in the "science" of calligraphy.

The *Australian Medical Journal* for September contains, among other useful and readable matter, notes by Dr. S. D. Read, the resident surgeon at St. Vincent's Hospital, Melbourne, of two cases in which an erroneous diagnosis was made owing to symptoms, in the one case due to intestinal obstruction and in the other to hydatids, being ascribed to the presence of ascaris lumbricoides in the intestinal tract. In each case a round worm had been vomited, and subsequent symptoms, due to different pathological conditions, had been considered the result of the parasite. The patient with a hydatid cyst made a good recovery, but the patient with intestinal obstruction died without surgical interference, the difficulty of diagnosis being further complicated by the fact that her bowels were moved after admission to the hospital.

Science Progress for November is interesting because of two biographies which it contains. Dr. William Stirling contributes an admirable *résumé* of the work of Carl Ludwig, the Professor of Physiology in the University of Leipzig; and Dr. Sims Woodhead tells exhaustively and with learned appreciation the story of Pasteur's life and scientific work.

The *Birmingham Medical Review*.—The November number attains the usual standard of excellence. Dr. Foxwell's paper on the Value of Cold Water Enemata in Uræmia is exceedingly interesting and contains a timely warning.

Blackwood's Magazine.—The Village of Perfect Health is described by an enthusiastic writer. It is an upland Swiss village near Aigle, and seems a veritable earthly paradise. Mr. W. B. Harris has a delightful paper on Kurdistan. He found the Kurd charming, and from personal experience we can agree with him.

The monthly magazines are of more than ordinary interest to a medical audience this month, and among others tha may be mentioned are the *Westminster Review*, in whicl Mr. Gilbertson writes on Immoral Ethics; the *Health News* which contains a Plea for Public Abattoirs, by Dr. Stephe Smith; *Sanitation in the West*, which prints an article o the connexion between Gymnastics and Hygiene; and th *Quirer*, wherein may be read a good paper upon East-en Doss-houses.

A DISTRIBUTION of the prizes to the Voluntee Ambulance School of Instruction will take place at Crosby hall, Bishopsgate-street, E.C., on Saturday, Dec. 7th, a 7.30 P.M. Lieutenant-General G. H. Moncrieff will present th prizes on this occasion, and a smoking concert will follow.

Analytical Records
FROM
THE LANCET LABORATORY.

STEARNS' MEAT JUICE.

(FREDERICK STEARNS AND CO., DETROIT, MICHIGAN; WM. A. RICHARDSON, 25, LIME-STREET, LONDON, E.C.)

WHEN it is known that a fluid consists practically of the juice of fresh, lean, uncooked beef expressed in the cold, its value as a nutrient does not require emphasising, for it will contain the albuminous constituents of the meat unchanged, besides also the stimulating extractive principles. This accurately describes Stearns' meat juice, which is a dark red liquid, turning semi-solid on the application of heat from coagulation of the albumin. The coagulum, which is the most important nourishing constituent, amounted at least to one-sixth of the total dry matter, the latter being equal to 44 per cent. The mineral matter consisted, of course, principally of soluble phosphate and a not excessive quantity of common salt. The taste is agreeably fresh and "beefy" and such that invalids would take it without reluctance. The preparation, judging from these results, should serve admirably where a vigorous nutrient is needed.

LYSIDINE (NEW URIC ACID SOLVENT). NOSOPHEN, ANTINOSINE, AND EUDOXINE (THREE NEW IODINE ANTISEPTICS).

JEYES SANITARY COMPOUNDS CO., LIMITED, 64, CANNON-STREET, E.C.

Recent clinical literature (chiefly German) has given records of the value of these comparatively new compounds which in the interests of curative medicine cannot be passed by. Lysidine, for example, has been employed, it is said, with remarkable success as a solvent for gouty concretions. Owing to its pre-eminently hygroscopic character it is conveniently obtained in the form of a 50 per cent. aqueous solution. It is an organic base, $C_4H_8N_2$, occurring amongst the products of distillation of ethylene-diamine, from which piperazine was derived. It is stated to possess, however, five times the solvent power on uric acid of piperazine, and sixty times the solvent power of carbonate of lithium. Lysidine is best administered in aerated water, although we read in a translation of a paper by Dr. E. Grawitz in the *Deutsche Medicinische Wochenschrift*, 1894, No. 41, that (referring to a series of cases of gout in which the treatment was followed by excellent results) "the remedy was administered to these patients dissolved in aerated water"! Nosophen is tetra-iodo-phenol-phthalein, containing in combination 61·7 per cent. iodine. Its internal administration (five to eight grains) is unaccompanied by toxic symptoms, but its chief important use appears to be as a substitute for iodoform, being free from odour and containing iodine in a more firmly combined state. The bismuth salt of nosophen is known as eudoxine, which has been employed for catarrh of the stomach and intestines, the presence of bismuth favourably modifying its action. Lastly, antinosine is the sodium salt of nosophen, which, while non-toxic and non-irritant, possesses greater antiseptic powers than iodoform, and has been used with advantage in rhinology and in the treatment of ear, mouth, and throat affections, and also in catarrh of the bladder.

MATÈ OR PARAGUAY TEA.

(A. CUMBERLAND, CATFORD HILL, S.E.)

It is an interesting fact that the leaves of the Ilex Paraguayensis, or Brazilian holly, were sought out by man, much as tea was, for the preparation of an infusion of peculiar restorative and "staying" powers, and that subsequently it was proved that the active principle of matè was identical with theine, which was, however, at first called paraguaine. Chemically, the composition of the infusion of the Paraguay tea-leaf resembles that of leaves of ordinary tea, Thea Sinensis (Camelliaceæ); but in certain important respects, from a dietetic point of view, the constituents exhibit markedly different properties. This is especially the case with the tannin principles. It is not correct to say that Paraguay tea contains no tannin; some chemists have reported as much as 15 per cent., an amount which is considerably in excess of most teas, or, at any rate, of mixed teas. In the sample of matè recently submitted to us we found by the lead method of Mr. Allen 8 per cent., and by the copper acetate method 7·76 per cent. This tannin, however, has very different properties from the tannin of tea. It does not, for example, coagulate gelatin or, what is the same thing, tan hides. This is probably a fact of great physiological or dietetic importance, since it is the astringency of ordinary infusions of tea which leads to disturbances of the digestive function either by acting prejudicially on the walls of the stomach or by rendering the nitrogenous principles of food tough and hard of digestion. Matè tea possesses the advantage, therefore, of being a refreshing and restorative beverage, due in a large measure to the theine it contains, without the evil effects of astringency. The liquor is pleasantly leafy and fragrant to the taste, somewhat resembling tea, but not of the same fulness and roundness of character, while its colour is pale straw. Nor does it possess that attractive, delicate aroma and flavour which in a good tea infusion are ascribed to essential oils. On analysis we obtained the following results: extractives, 35·60 per cent.; insoluble matters, 64·40 per cent.; moisture, 8·40 per cent.; mineral matter, 5·00 per cent., alkalinity of which was equal to 0·88 per cent. K_2O; tannin, by lead method 8·00 per cent., by copper acetate 7·76 per cent.; and theine, 0·45 per cent. The simple experiment of adding infusions of the same strength of matè tea and ordinary tea to a solution of gelatin—the former producing no coagulum, while the latter produces an abundant curd—is instructive, and would appear to indicate that matè tea may be taken with advantage by those with whom tea disagrees, while at the same time they would secure the refreshing and invigorating properties of the same active principle in its natural condition, the alkaloid of tea—theine.

PALATINOIDS OF PEPTONATE OF IRON AND SULPHATE OF MANGANESE.

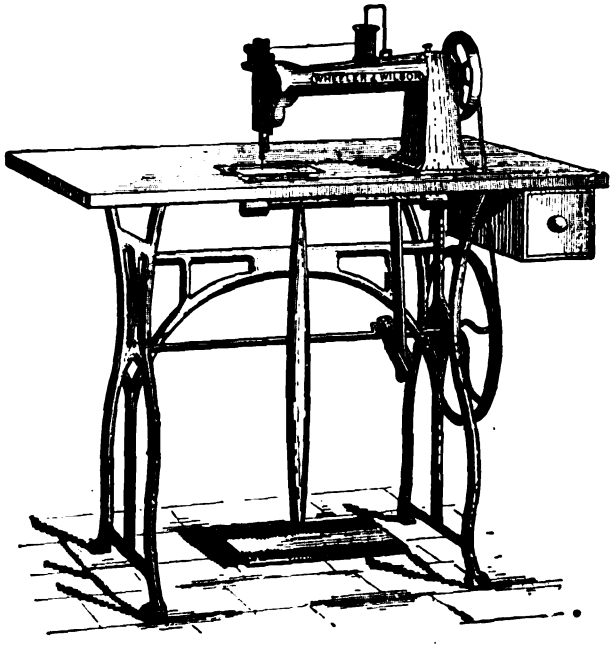
(OPPENHEIMER, SON, AND CO., LTD., 14, WORSHIP-STREET, E.C.)

Palatinoids, consisting of two air-tight jujubes of watch-glass shape joined edge to edge, offer an excellent means of preserving unstable bodies from the deterioratīng influences of air and moisture. A recent addition to an already valuable and long list is the palatinoid of peptonate of iron (one grain) and sulphate of manganese (one grain). This combination has been found very serviceable in the treatment of chlorosis and anæmia.

TERRŌL.

(THE TERRŌL CO., 30, 32, AND 34, DEVONSHIRE-ROAD, FOREST HILL, S.E.

The introduction of a refined hydrocarbon oil as a substitute for cod-liver oil in, as it is asserted, diminishing waste in phthisis and in other conditions demands the attention of the profession. Once accepted that it is the oil that is the remedy, then the theory of the active principles of cod-liver oil must break down, and the only explanation of the well-known therapeutic value of carefully extracted cod-liver oil that remains must be its peculiar digestibility. The purity of terrōl is, at any rate, a very important factor in its favour as regards internal administration. It is a bland, perfectly tasteless and odourless hydrocarbon of the vaseline type. It is viscid at 16° C., but slight warming suffices to convert it into a clear, yellow, and highly fluorescent oil having a specific gravity of 0·864 at



Digitized by Google

100° F. It is said to have been used with excellent effect in the relief of chronic bronchial catarrh, and in ministering to the waste of pulmonary and other diseases and in affording an easily assimilated nutrient in cases of faulty nutrition. Terrōl is proof against prejudicial oxidising influences, and, unlike vegetable oils or those of animal origin, never becomes rancid. It possesses a high degree of purity, which is imperative in all preparations, and especially hydrocarbon oils, intended for internal administration, and its absolute tastelessness is a very important feature.

New Inventions.

AN IMPROVED MOTOR FOR SEWING MACHINES.

SEWING machines adapted for useful general work are invariably driven by a treadle to which either one or both of the feet may be applied. The ordinary treadle answers well for the stitching of exceptionally stout materials and for the purposes of various machines driven with the foot by men such as turners or printers, but for average sewing machine work it has the drawback of requiring more effort than is necessary. This extra fatigue is a serious consideration in the case of females employed all day long at the machine, but an ingenious modification of the ordinary treadle has now been introduced by which the labour of the worker will be greatly economised without any sacrifice of efficiency. As is well known, the ordinary treadle is horizontal when at

rest and has to be forcibly depressed by the foot in order to turn a fly-wheel by means of a crank. In the new system the fly-wheel and crank are retained, but the horizontal treadle is replaced by a vertical one which is hinged to the under side of the table on which the machine rests, and hangs down almost to the floor, where it ends in a horizontal platform for the foot. The worker's foot is not moved up and down to drive the machine by pressing the treadle, but produces the same effect with less labour by a gentle swinging of the foot backwards and forwards. The muscles chiefly employed are the flexors and extensors of the knee-joint, and the weight of the foot and leg is, of course, supported by the platform on which the foot rests. An important advantage is that the continual movement of the thigh, inevitable under the present system, is so diminished as to be hardly perceptible. The "Hygienic Motor" is the appropriate name of the new invention; its principle is sound and the details are extremely simple. The ordinary treadle is employed to most advantage when the fly-wheel is comparatively heavy and the operative stands at the machine; but for seamstresses who sit all day long at the machine the to-and-fro movement of the foot is less exhausting than the alternate upward and downward movement which has hitherto been required. The new system can be readily adapted to any of the existing kinds of sewing machine, and is manufactured by the Hygienic Motor Company, Grafton-chambers, 120, Tottenham Court-road.

A NEW CARRYING CHAIR.

MR. JOHN CARTER, of New Cavendish-street, Portland-place, has brought out a new carrying chair which appears to possess certain advantages worthy of the recognition of the profession. It is constructed of iron cased with wood,

with two leading wheels, and is suitable for the conveyance of invalids under most circumstances. It could be at once rendered serviceable either for use in a house with a difficult staircase or in case of accident in the street, on rail, on ship-board, or for military purposes as a stretcher, and, in addition, the price is moderate.

AMBULANCE FIRST AID.—Mr. Casper R. Laurie, L.R.C.P. Lond., M.R.C.S., of Redruth, honorary surgeon of the Redruth St. John Ambulance Brigade, has presented the brigade with a solid leather case containing all the appliances necessary on rendering first aid to the injured.—The members of the Featherstone local railway branch of the St. John Ambulance Association have presented a gold ring to Dr. Steven, the lecturer to the class.

THE CARDIFF INFIRMARY.—At a meeting recently held at Cardiff in connexion with the infirmary it was stated that at present there were 120 in-patients in the infirmary, and when the new wards had been opened the number would be increased to 180. This extension had cost £14,000, and £7000 of this were required. The new wards could not be opened for lack of funds. Lord Windsor's proposition that a bazaar should be held to pay off the debt of £7000 was unanimously carried.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 16, 1895.

THE annual general meeting of the Fellows and Members of the Royal College of Surgeons of England, which took place on Thursday, Nov. 7th, was by far the most interesting and important general meeting which has been held at the College for several years. There was a marked improvement in the attendance and in the tone, temper, and speeches of the Members of the College, whilst the resolutions proposed in the interest of the Members were of a moderate and practical character. There was an air of genuineness about the proceedings which has been lacking on some former occasions, and the unanimity of opinion which prevailed was admirable and has materially advanced the cause championed by the Society of Members. As a matter of tact, taste, and good feeling it would probably have been better if no objection had been raised to the adoption of Surgeon-Major INCE's usual motion according the thanks of the meeting to the Council "for the interesting and important report presented," but there was nothing churlish or offensive in the mode in which the amendment to pass to the next business was proposed by Mr. GEORGE BROWN and seconded by Mr. BRINDLEY JAMES, and it was natural that in view of the solid business on the agenda paper there should have been a strong desire not to waste the time or fritter away the energies of the meeting. The points emphasised in the motion standing in the name of Mr. JOSEPH SMITH were the most vital points of reform which could have been selected, and professional opinion generally would be found to lean in a preponderating force in favour of the propositions therein embodied. In its original form the motion ran as follows: "That this meeting requests the Council to take steps to obtain an amended Charter which shall contain the following provisions: (*a*) that no alterations in the constitution and external relations of the College shall be effected without the consent of the body corporate, convened to discuss such alterations; (*b*) that the present annual general meeting be made statutory, and that the report of the Council shall be submitted for formal adoption; (*c*) that the members of the Council be increased to thirty-two, and that eight of these, who may be Members, shall be elected by the Members only, provided always that no Member who has not been a Member for twenty years shall be eligible for a seat on the Council."

On the suggestion of the President this tripartite motion was formally divided into three separate resolutions, each of which was proposed by Mr. JOSEPH SMITH and seconded by Mr. DICKINSON, and carried all but unanimously. The first resolution involves a principle which has been recognised by the Council, but not to the full extent of its signification, and has certainly not always been acted upon by that body. The exclusion of the Apothecaries' Society from the Conjoint Examination and the whole arrangements for that examination were effected by the Council without reference to the body corporate, and the proposed coöperation with the University of London was decided upon by the Council first, and then brought before the Fellows and Members for discussion. The second resolution embodies a point for which we have always contended—viz., that the annual meeting of Fellows and Members should be statutory and not left as at present to the good pleasure of the Council to hold or to withhold as that body may please. It is for the good of the institution that the management of the College should be submitted every year to the criticism of the Fellows and Members, and that all temptation to the Council to interfere with its continuity should be removed. Moreover, if the meeting were statutory, the Fellows and Members would have a freer hand, and the conduct of the meeting would be brought more into line with the conduct of other general meetings elsewhere. The third resolution, providing for the addition to the Council of eight representatives of the Members of the College, affirms another principle for which THE LANCET has long striven, and gives effect to that principle in the way which is open to the least objection, inasmuch as it would deprive the Fellows of no real privilege which they at present possess, and would leave them to all intents and purposes still in undisputed possession of the control of collegiate affairs. All that it would take away from the Fellows is the *exclusive* right of electing members to the Council, and this is a perquisite which undoubtedly a large number of the Fellows would rejoice to be able to abandon. The whole history of the present century is a history of successful struggles for the destruction of the exclusive privileges possessed by particular classes in the community. Disabilities have been removed from Roman Catholics and Jews, close boroughs have been abolished, municipal bodies reformed, and the franchise extended to the working classes, and by all these reforms the State has been enormously strengthened. Reasons of a similar character to those which were urged in favour of these changes can be adduced fo the removal of disabilities in the medical profession. How greatly would the Royal College of Surgeons of England gain in power and influence by the contentment and elevation of its grand constituency of members. Accidental circumstances have delayed this concession of representation to the Members and the consummation of an act of good policy and justice, but these reforms cannot be much longer delayed without seriously weakening the institution and rendering still more critical the present critical state of its finances. Elected as the Council of the College at present is by the Fellows alone, it could not of its own good pleasure and mere motion at once accede to the request of the Members—the Fellows of the College must first be consulted. It may be said that the Fellows were consulted some years ago and that the answer was not favourable to the claims of the Members, but the circumstances under which they were consulted were widely different from those prevailing at the present time, and the mode in which they were consulted was so oracular and ambiguous that it was not a fair test of the balance of opinion; and yet even under such adverse conditions the number of the Fellows prepared to do justice to their fellow Members was considerable. Moreover, the present proposal is in a form which

Digitized by Google

deprives the main objection to the original proposals of all its force. The cry then was that the Fellows would be swamped at the poll, and that the Members of the Council would be elected no longer by the Fellows but by the Members of the College. This cry cannot be uttered again. So that now there is every reason for consulting the Fellows of the College again, and if the Council puts the matter on one side and takes no action whatever, a grave responsibility will be incurred. There were many Fellows at the annual general meeting, and but one was found to hold up his hand against the third resolution, and several Fellows there were who held up their hands in its support. A gradual process of conversion is proceeding amongst the Fellows of the College, and if the Council of the College were now again to consult them, either by circular or at one of the half-yearly meetings, we should be greatly surprised if the opposition to the concession of representation to the Members of the College did not prove altogether insignificant.

About the question of the admission of women to the examinations for the diploma of the College, which occupied the remainder of the time of the meeting, little need be said, for the adverse decision of the Fellows of the Royal College of Physicians of London had deprived the discussion of any immediately practical importance. The result of the voting showed that opinion on this subject is nearly equally divided, and it was curious to note that the fact that so many portals had been opened to women for obtaining medical and surgical diplomas was used as an argument both in favour of admitting women and in favour of excluding them from the examinations for the diploma of Member of the Royal College of Surgeons of England. For the time being the question is probably settled, but so great has been the change of opinion in the profession on the general question that when the next application to the two Royal Colleges of London is made by the London School of Medicine for Women no one need be surprised if the present decision should be reversed at both institutions.

THE medical officer of health does not lie on a bed of roses, but his object is to make his district sweet and healthy. His pride must be to have it in such a sanitary condition as will compare favourably with that of other districts similar in size, situation, and population. His powers under recent Acts are certainly great and admit of being used in a way which to some, especially to the owners of property, may seem harsh and tyrannical. But his responsibilities are great. The law has recognised this and has made it the interest of large communities to pay such salaries to their medical officer as to make him independent of private practice, and has still further secured his independence by making his dismissal by the sanitary authority conditional on the consent of the Local Government Board. Preventable disease, as His Royal Highness the Prince of WALES said, ought to be prevented. The prevalence of it is the opprobrium of the sanitary authority, and ultimately of the medical officer of health, on whose advice chiefly the sanitary authority acts. The Acts under which such powers are conferred are comparatively new. The property in regard to which they are used is for the most part old. Hence it is not difficult to understand that a serious collision of feeling is apt to happen between the sanitary authority in its intolerance of preventable disease and the owner of property that answered all the old-fashioned purposes of property, and especially that of returning a good rent to its owner, but which is capable of harbouring or emitting poisons which either kill outright or tend to degrade the health and *morale* of the inmates.

A sharp collision of this kind may be studied at the present moment in the case of Islington. Mr. ERNEST EDWARDS, Secretary of the Metropolitan House Investment and Agency Company, Limited, has addressed a letter, which we publish in another column, to every member of the Vestry of St. Mary, Islington, to the vestry clerk, and to the *Islington Gazette*, complaining bitterly of the way in which the sanitary authority of Islington and its medical officer are using the powers conferred on them by the Public Health Acts. Mr. EDWARDS shows that his company owns 68 houses in the parish, and collects the rents of 51 other houses, making in all 119 houses, of the aggregate net annual ratable value of £3500, or thereabouts, and representing an invested capital of £40,000. He states that all the houses are in excellent repair, and all let to most respectable tenants, the rentals varying from £30 to £50. He complains of the constant demand of the sanitary authority on the company to have the drains entirely relaid, ventilation shafts erected, &c. The cost of such alterations is from £20 to £35. Mr. EDWARDS alleges that the houses of the company are made the special objects of the sanitary authority's attention and demands in a way in which other property is not. But he may be comforted in this respect by a similar complaint addressed to the *Islington Gazette* by Messrs. NOKES and NOKES, who manage ouses in Islington and other parts of London for various lients, and who allege that the demands of the sanitary authority are "far more numerous" than in any other parish. These gentlemen go so far as to suggest that a petition should be presented to the Local Government Board asking for an inquiry to be made into the management of the sanitary department of the Islington Vestry. The same grievance is expressed in the same paper by Mr. C. J. GARD on behalf of the "Central Property and Investment Company." He declares that owing to the fads of the sanitary authority property in Islington is hardly worth having. He makes a still more serious charge, which the Islington authorities would do well to call on him to establish, that they serve notices to do work "on people which the department knows it cannot enforce by law."

We cannot pretend to decide between parties whose point of view and whose interests are so different—our sympathies are naturally with all reasonable attempts to make houses fit places to live in. Toleration of ill-laid drains or inadequate and defective waterclosets on the part of landlords is next thing to a crime. They convert the house, which ought to be a means of life and health, into a source of disease, and possibly into a death-trap. We have no sympathy with mere "fads," or with mere gratuitous exactions from owners of property. In all conscience local rates are high enough, and local indebtedness is increasing

Digitized by Google

fast enough, without giving any encouragement to the wanton use of great powers conferred only for grave public purposes. But do these letters establish any such case against the Islington authorities? We think not. Two things strike us in the letters—firstly, they are written by the representatives of companies, and companies are apt to look very much to their own interests, and to be out of sympathy with the tenant's view and case; and, secondly, they are reticent as to the health of the tenants. They do not tell us whether they have had sickness on the premises or other reason for complaint. Now this omission is radical. But it is supplied by Mr. HARRIS, the medical officer of Islington, in a letter to the Local Government Board on Mr. EDWARDS'S letter. Mr. HARRIS says that "in every instance the premises were visited either by reason of the occurrence of infectious disease or through complaint having been made to me of their insanitary condition." The alterations may have been excessive, but unless this statement can be refuted we must assume the contrary. £30, or £35, may seem a large sum to owners of property; but it does not seem a large sum to make faulty houses permanently sound in a sanitary sense. The contest is an interesting and an inevitable one, but public sympathy will be with the law that requires a landlord to put his house into such a condition that it shall not endanger life or even health. Islington is the most populous parish in England, and sanitarily compares favourably with most other metropolitan parishes, and even with some rural ones. The general death-rate of Islington and the death-rate from zymotic disease are markedly less than in any of the great groups of sanitary areas as given in the last quarterly return of the Registrar-General (July, August, and September). This, in the long run, must be in the true interest of the parish and of its property owners.

THE report of the last quarterly meeting of the town council of Lowestoft includes a discussion on public health matters which would afford amusement to many were it not that the interests of health and life are involved. Lowestoft had a heavy rate of mortality during the month ending Oct. 19th; it reached no less than 50·18 per 1000, 19 per 1000 being due to measles and 10·3 to diarrhœa. Monthly rates are not often of much value, but this one is so excessive that it called for investigation, and the medical officer of health did his duty in reporting on it to the sanitary committee. This led to the chairman of that committee condemning the principle of such reports being "reduced to writing" and hence becoming known to the public, with the result of damaging what he calls "the general interests of the borough." If this chairman means that visitors are thus temporarily prevented from visiting Lowestoft, then his suggestion as to privacy pending an epidemic of measles is one so intolerable that we trust it will be resented by his own constituents. Can he possibly mean that he wants, by a policy of secrecy, to attract families with young children to a place where they will run an exceptional risk of death? But we cannot take this chairman *au sérieux* in view of his next statements. First, he announced that the medical officer's views as to the cause of this exceptional mortality were wrong; they were, indeed, "but the opinions of one man," whereas he (the chairman), who disclaimed all medical training, though "but one man," had had his "own experience," which enabled him to "trace a disease." The results of his etiological investigations were next propounded by means of an announcement, which he saw no objection to make quite public, to the effect that the sewers of Lowestoft were inadequately ventilated and gave forth offensive odours, and "were a fruitful cause of disease." The public will note this frank declaration of the chairman of the sanitary committee, who evidently will have no secrecy when his views as to the state of the sewers are in question, and they will not forget what the medical officer of health says as to the condition of the middens in relation to a diarrhœa death-rate of 10·3 per 1000 of the population.

The next point discussed was a definite proposal to include measles among the notifiable diseases, the proposer reminding the council that both the present and former medical officer of health had advocated it. But it seems to be the practice of some in Lowestoft to deal with health questions in a spirit of levity, for a second councillor immediately urged that such a recommendation should "not be taken too seriously," especially as it related to a "comparatively innocent" disease—one, he forgot to add, that kills from 11,000 to 16,000 of the population of England and Wales every year—and then this authority on public health actually announced that "he did not know a town n which measles was included in the list of notifiable diseases." We cannot, of course, take him "too seriously" as to this, otherwise his constituents might suggest to him to learn the elements of his duties before he next addresses an audience on a matter so serious as that relating to public health. Fortunately, the Mayor diverted the discussion into a serious groove and announced that if notification of measles could stay such a grave mortality "it was worth any expense, no matter what.' For his information we may say that the question of the notification of measles is a difficult one. Where the notification has been properly used at the onset of an epidemic by strictly preventing children from going to school from infected houses it has achieved excellent results; where that early stage has been allowed to pass without careful attention to the question of school attendance in every case, the expenditure on notification has been wasteful, and the subsequent closure of schools often useless.

Indeed, the question whether in a given place exclusion from school of infected scholars or total closure of schools should be practised must be a matter for medical judgment. No general rule can be laid down as to the inclusion of measles as a notifiable disease. It mainly depends on the use to which the newly acquired knowledge will be put; but it also depends on other local circumstances. The whole matter is, we are informed, being studied by the Medical Department of the Local Government Board, but the problems involved are numerous. One thing we believe to be certain—namely, that if properly used in a place like Lowestoft, such notification ought substantially to save life and prevent needless interference with elementary education.

THE Bradshaw Lecture, delivered by Dr. BRADBURY before the Royal College of Physicians of London, and

Digitized by Google

published in another column of our present issue, forms an interesting record of the extension of investigations over ground which has already attracted many experimental workers. The possibility of influencing the size of the arterioles, and of thus regulating the supply of blood to the capillaries, has long fascinated experimental physiologists, while the evils of high tension have been more grudgingly allowed in some directions by clinical observers. It has been freely admitted that some cases of angina pectoris were benefited by employment of nitrite of amyl and of nitro-glycerine, and these substances have been freely employed in various ways. The gains from nitrite of amyl have often been found to be evanescent, although it has the advantage of rapidity of action, while nitro-glycerine, although its effects last somewhat longer, has often given rise to headache, and even now it can scarcely be said to have found general acceptance at the hands of the medical profession. The fact is that the nitrites already known and nitro-glycerine agree in being at once too powerful in action and too transient in effect, and more recent researches have been directed towards the discovery of some substances able to produce a prolonged fall of blood pressure. Dr. BRADBURY mentioned the work of previous investigators—LEECH, MATTHEW HAY, and LAUDER BRUNTON—and he indicated the reasons which had led him to work more particularly with the nitrates of the higher alcohols and their allies. It is needless here to follow his account of the preparation and properties of the bodies with which he chiefly experimented—viz., erythrol tetranitrate and mannitol hexa-nitrate—but the experiments by which he has determined their pharmacological actions will be found to be careful extensions of the methods of previous workers, and they appear to prove conclusively that these substances possess an action similar to that of nitro-glycerine, but that their effects are weaker, though more prolonged. He employed the perfusion method of LUDWIG to determine the purely local action of these bodies, and he found that for practical purposes the general effects were the same when the experiments were conducted with the organs of warm-blooded or cold-blooded animals. These experiments were confirmed by blood pressure tracings from rabbits under the influence of urethane, and further by pulse tracings from actual patients. One of the most interesting features of the lecture was the exhibition of a diagram showing the relative effects of the various members of the "nitrite group," in which the nitrates of erythrol and mannitol were shown to be inactive during the period immediately following their administration, while their effect, which was gradually produced, was markedly prolonged.

The practical outcome of these experiments, the application of these new vaso-dilators to suitable cases of disease, must naturally form the most attractive feature of this series of experiments, and here Dr. BRADBURY appears to tread upon less certain ground. It will be noted that he speaks of diseases in which these drugs *might* prove useful, instead of giving details of cases in which they have already established their claim to consideration. Admitting all that can be said in favour of "diminishing the work of the heart and the pressure upon each unit of area of the artery," we imagine that most practitioners might feel some hesitation about the advisability of attempting "to keep the tension constantly below a certain level." It is possible that angina-like pains may be not only relieved by nitro-glycerine and nitrite of amyl, but even averted by the longer acting remedies such as erythrol nitrate, and that in this direction the new vaso-dilator may find its future scope of usefulness. But Dr. BRADBURY himself admits that many cases of cardiac pain are better treated with morphine than with vaso-dilators, while for others he notes the value of purgatives and of attention to the general health. With regard to chronic Bright's disease, the condition which beyond all others is associated with a high tension pulse, it is possible that many of the troublesome symptoms—headache, mental ineptitude, weariness, and the like—may be relieved by the new vaso-dilator, but it must not be forgotten that many observers claim that the high tension in this disease is the result of conservative changes in the vascular walls, which tend to protect the tissues from an impure condition of the blood; while relieving symptoms, therefore, by the administration of vaso-dilators, it must be remembered that simultaneous measures must be taken to rid the blood of impurity so far as possible. The other conditions enumerated by Dr. BRADBURY—aneurysm, Raynaud's disease, various forms of dyspnœa, the headache of high tension and various forms of nervous diseases—may perhaps be found to offer more suitable fields for employment, but this is for the future to determine. Dr. BRADBURY is certainly to be congratulated upon the introduction of new drugs which will keep down the blood pressure for a length of time; but their future employment will depend largely upon the view taken of the evil effects of high arterial tension. Meanwhile, although in their infancy, it is satisfactory to find that no evil effects have yet followed their administration; but it is disappointing to learn that they do not produce certain results in all cases and that some individuals are insusceptible to their action.

Annotations.

"Ne quid nimis."

MUNICIPAL HONOURS TO MEDICAL MEN.

IT is not every medical man, however much he may desire to do so, who can find time to attend to the manifold duties involved in the office of mayor, but in few other capacities as a citizen does the medical man possess more power for good than as the occupant of the civic chair. As a medical man he should be fully acquainted with the sanitary and hygienic needs of his borough, and the position of mayor offers excellent opportunities for seeing that the necessary reforms are properly carried out. We are sorry, therefore, to note that the list of medical mayors this year falls considerably below the average. Up to the present we have only been notified of four: Dr. E. Jepson, Mr. Richard R. Daglish, Dr. T. W. Thursfield, and Mr. H. F. Townshend Chambers. Of these the first three have been re-elected. Alderman E. Jepson, M.D. Durh., &c., was elected mayor of Durham last year and re-elected this year for another term of office. He has rendered good service to his borough by endeavouring to

Digitized by Google

educate his fellow townspeople in sanitary needs, by urging the provision of a hospital, and by having the Notification of Diseases Act adopted. He has repeatedly agitated for better dwellings for the working classes, the homes of such people in the ancient city of Durham being about the worst to be found in the kingdom. He has been a town councillor for about eight years and has just been raised to the aldermanic bench. Alderman R. Daglish, J.P., M.R.C.S., &c., the mayor of New Romney, was elected to the office of chief magistrate in 1885, when the borough received a new charter. He was re-elected in the following year and in 1888. Last year he was again chosen to occupy the civic chair, and has been re-elected this year. Alderman T. W. Thursfield, M.D. Aberd., F.R.C.P. Lond., &c., was born at Kidderminster in 1839. He is a Justice of the Peace for the county of Warwick and for the borough of Leamington. Fourteen years ago he entered public life as a member of the Free Library Committee of Leamington, and two years afterwards he became a member of the town council for the north-east ward of the borough, which constituency he has represented ever since. In November of last year he was elected mayor of Leamington and has now been re-elected. Mr. H. F. Townshend Chambers, L.R.C.P. Edin., &c., settled in Wareham in 1892, was elected councillor in 1893, and elected to the office of chief magistrate in the present year. He holds a commission as surgeon-lieutenant in the 1st V.B. Dorset Regiment. To these gentlemen who have been chosen as the recipients of the highest municipal honour which their fellow citizens can bestow upon them we offer our congratulations.

A TEACHING UNIVERSITY FOR LONDON.

THE movement in favour of establishing a Teaching University in London is again showing signs of activity. A meeting of the teachers in the medical schools will be held on Wednesday next (the 20th inst.) to urge the Government to push forward a Bill, on the lines of Lord Playfair's Bill, for the appointment of a Statutory Commission to deal with the recommendations of Lord Cowper's Commission. The delegates from the various institutions affected by the recommendation will meet at Burlington House on the next day to arrange for a deputation, which Lord Kelvin will introduce, to wait on the Duke of Devonshire and Sir John Gorst. The deputation will be received either at the end of November or early in December.

MEDICAL PRACTICE AND PUBLIC CONFIDENCE.

SOME stories are so preposterously realistic that it is only after some hesitation that we give doubt the benefit, and the tale is treated as a serious joke. To this class belongs a curious report which, if true, illustrates in a truly diagrammatic manner the wrong-headedness of some patients respecting the scope of medical skill and duty. A man had been operated upon by a well-known surgeon. Two days afterwards a revolver was found under his pillow and removed. Questioned by his nurse, the patient explained that he had secreted the weapon, intending, had his wound proved troublesome, to shoot, first the surgeon, then himself. Perhaps the story is a mere fiction. For the patient's credit we may charitably hope it is. A more pitiable instance of childish vindictiveness and ingratitude it would be very difficult to discover. Perhaps it might not be impossible, however, to quote instances of a somewhat similar folly. Mistaken violence is the natural weapon of ignorant and passionate natures when confronted by danger or misfortune. It is unfortunately by no means peculiar as might be supposed, to savage peoples, though it may very properly be regarded as an evidence of moral reversion. The usages of civilisation, having better sources of inspiration, are as a rule more orderly. Commonly, too, they are more intelligent, but not always. Even under the light of modern science the practice of medicine remains to most persons a book which, though not sealed, is largely illegible. Still, therefore, it claims the confidence of mankind as an essential to its beneficent operation, and this trust has been freely accorded to the profession by the common consent of most rational persons. We will also take it upon us to say that it has been treasured and safeguarded by the recipients with special devotion to the public interest. Under no system, however, can we expect to arrive at perfection, and we need not feel greatly surprised to find that a certain cautious reserve often accompanies the actual working of this agreement. It must, after all, be remembered that in individual cases confidence comes largely by experience. On the other hand, there are those in whom the tendency to self-concern is unduly developed. This is more especially true of some who possess a slight though imperfect acquaintance with medical principles. Beguiled by their partial knowledge, they occasionally display their independence of qualified medical authority in ways which are highly objectionable. Sometimes we find them posing as quasi-professional authorities on their own account and recklessly distributing supposed "cures" of uncertain character. Should they at any time submit themselves to the guidance of a duly instructed practitioner their submission is really a delusion. Easily dissatisfied, impatient, incapable of reasoning correctly, they are continually interfering to alter their modes of treatment according to the teaching of some newly imagined system. Their sense of indebtedness is in keeping with their conduct generally, and, like the misguided individual whose revolver was so timely removed, they not uncommonly attribute the inevitable ills of disease to the supposed error or neglect of medical attendants. Patients of this ignorant and ungrateful type are, happily, exceptional in medical practice. We have seen that they illustrate in an eminent degree the bad qualities of self-confidence and distrust of others, which practitioners with whom they come into contact can best disarm by a constant and close adherence to the straight line of professional duty, a course which cannot fail to be attended by the proofs of capacity.

CORONERS' JURIES AND VIEWING BODIES.

AT the quarterly meeting of the Lancashire County Council at Preston on the 7th inst. the subject of the reform of coroners' inquests was dealt with. The Finance Committee reported that after consultation with the coroners they had agreed to the proposed abolition of the viewing of bodies by the jury, and that the jury should be reduced from twelve to seven or eight. Both these changes, it should be remembered, will require the amendment of the Coroners Act, 1887, Sections 3 and 4. We cannot see any reason why the number of jurors should not be reduced to the same number as those in a county court, which is five. The viewing of the body by the jury or its abolition is a much more debatable point. If every coroner were by his medical training and experience competent to perform this duty it might suffice to have the body viewed by him and the relative or other person who could swear to its identification. Or if the verification of the body should ever form an integral part of our death registration system, the viewing of the body by the jury would cease to have its present value, but in the existing state of our present system registering deaths and burying bodies the only deaths really verified are those concerning which inquiries are held by coroners. The Finance Committee of the Lancashire County Council also suggested that a medical report should be supplied at a fee of 5s. when required by the coroner; they are kind enough, however, to add that "this fee would,

Digitized by Google

of course, not include that for a full post-mortem examination"! During the past year there had been 1764 inquests, mostly formal, but requiring the attendance of 21,168 jurymen. With reference to the payment of 5*s*. for a medical report, we may remark that a guinea is always paid for such a report made in Scotland to the procurator-fiscal, a guinea extra being paid for a necropsy. As such a medical report may have the effect of dispensing with the formality of an inquest, we cannot expect that the medical practitioners in Lancashire and elsewhere will be satisfied with so shabby a remuneration as 5*s*. Considering the number of inquests, the circumstance that they were mostly formal, and the fact that the Lancashire county coroners are, with two exceptions, all legal coroners, we would observe that probably many of these inquests were altogether unnecessary. Mr. Oliver Pemberton, the able medical coroner of Birmingham, who succeeded a legal coroner, has reduced the number of inquests very considerably, while at the same time perfectly safeguarding the public interests. Nor is this surprising. To decide whether an inquest shall or shall not be held is a matter which comes home to a medical coroner from the moment of his appointment; it can only be acquired by a legal coroner after years of experience and, we may add, of painful experiment.

PAYMENT AND CHARITY IN HOSPITALS.

WE have always maintained that medical systems of charitable relief can be justified only by the necessitous condition of those whom they are intended to assist. They confer no privilege or gratuity upon any one class. Poverty alone constitutes a title to such aid wherever it supplants the ordinary method of remuneration for services rendered. It is idle to talk of hospital privileges in connexion with any one section of the community. Not even the artisan population can lay claim to them as in any sense a natural inheritance. Many ailments of greater, as well as of less, importance occurring among members of this class are capable of efficient and economical treatment at home, and there they ought to be treated in accordance with the ordinary rules of medical practice. The club member's penny a week is in its way a protest, though a most inadequate one, against indiscriminate giving. This system of payment, however, though conceivably capable of development, is still but a stunted growth if its expected fruits are those of mutual advantage. Its frequent abuse is notorious. Even more unfair, both as regards the giver and receiver, is the novel practice on the part of some hospital authorities of conceding with the same generosity as they do to the poor the best efforts of medical and surgical skill to persons accustomed to live in comfort and even in affluence. Naturally enough this more recent movement has been watched with some anxiety by general practitioners. These gentlemen, it must be remembered, are entitled to expect that in placing their energies unreservedly at the service of the sick they will at least be secure against needless interference. More especially may they expect to receive due consideration from those of their medical brethren who hold office on the staffs of hospitals. We cannot admit that recent developments of the hospital pay system have reflected this ideal of justice. The miscarriage of charity, possible under any circumstances, is almost an essential part of that arrangement which proposes to admit as ordinary inmates of the wards at a small inclusive weekly charge persons in the middle ranks of life and well able in many cases to pay the usual fees of medical practice. We do not forget to allow for domestic difficulties. The stranger travelling, the bachelor in lodgings, the invalid in a family every member of which follows an occupation—these and others would recognise the advantages of admission to hospital. No less would those to whom they must otherwise look for the comforts and attentions of home life. We admit all this, but we maintain that the pay hospital does not provide the best answer to the question what to do. What such an invalid requires is not that he should be taken over by the hospital as a sort of universal provider at a minimum, we might be paradoxical enough to say at less than a minimum, cost. He requires only that the present and actual emergency of illness should be adequately met. In many cases attendance at home is quite sufficient. There may be no great expense entailed in treatment, and the patient, though necessarily a constant inmate, is not a heavy burden on the care of his neighbours. Where his removal is absolutely necessary an invalid home conducted somewhat on the hotel system may best receive him. Such establishments are already in existence. The object of those who enter them for the purpose of treatment is not mere economy, nor is it the supposed advantage of greater medical skill; it is that they may divest others of the responsibilities which their illness entails, without forfeiting the comforts of home, such nursing attendance as may be required, or the needful supervision of the medical adviser whom they may select. This arrangement has really, beyond a superficial resemblance at first sight, nothing in common with the hospital system. The latter has arisen and grown up in the name of charity, it has been employed until recent years avowedly in the interest of the poor alone, and it has not appealed except on behalf of the poor to the well-to-do classes. Any other course of action must involve a a dilemma. Either charity and economy must be equally lost sight of, and professional service, whether of practitioners or nurses, added to the cost of residence, will leave the patient where he was before admission, or we must accept an alternative which is in its way more generous than just. In this case an economy must be effected somewhere. If it be not at the expense of the means of treatment themselves it must be at that of practitioner or nurse. If at the cost of either of the latter, then members of the hospital staff are brought into a state of unbecoming rivalry with their comrades in the work of healing outside the hospitals. We cannot, indeed, see wherein the necessity lies for this inconvenient system of payment by hospital patients or what are its advantages. An arrangement such as that we have above suggested is clearly preferable, since it secures for the sick the same benefits, while it should not injure the just interests of any whom it may concern.

THE JACKDAW.

MR. W. J. C. MILLER, the Registrar of the General Medical Council, is wont to amuse himself *procul negotiis* by making and writing very charming studies of bird-life, as all our readers know. In this art he ranks with Phil Robinson, with E. H. A., and the writer of "The Tribes on My Frontier," for he sees and notes down all the little ways of his much-loved subjects. His last contribution to *Nature Notes* is on the Jackdaw—a fellow of infinite fancy, like all his tribe. Less malignant in his mischief than the raven and infinitely more gentleman-like than the crow, who is the rough of bird society, the jackdaw has afforded material for a variety of tales and stories. Mr. Miller refers to the one of Rheims, to Cowper's, for whom, as rendered into Latin by "Vinny" Bourne, we conceived a violent distaste in our school days; but he does not mention the fact that to see *one* jackdaw was a presage of woe worse than one magpie. When the present Clifton Suspension Bridge was in course of erection, a jackdaw daily sat upon the one chain which for some time was the sole representative of the bridge. The workmen noticed this, and very shortly after one of them was killed. However, as a set-off

Digitized by Google

against this we have the jackdaw—if cornix can be taken thus—in Ovid:

"Tarpeia quondam predixit ab ilice cornix
Est bene, non potuit dicere, dixit erit,"

a prophecy which delighted Thomas Fuller. One word more of thanks to Mr. Miller: he describes a delightful haven of rest on the south coast and mercifully does not say where it is. So it will remain unspoiled by the tripper.

HIGH TEMPERATURES.

WE have received a reprint of a paper by Dr. A. Jacobi of New York relating the case of a man who received an injury to the head and whose rectal temperature upon two occasions registered 148° F. Dr. Jacobi gives most careful notes of his case, but for all that we do not believe that the temperature shown by the thermometer was really the temperature of the man. Temperatures of 113° to 115° have not infrequently been recorded *after death*, when there can be no suspicion of fraud; but we should be very sceptical of the genuineness of any over 111° during life. Undoubtedly cases in which every care has been taken to obviate fraud of any kind have been recorded in our columns, but where the thermometer sometimes registered 117°. Dr. Jacobi's patient was a typical neurotic, who after he had heard any symptoms talked about generally managed to exhibit the same. For instance, the notes say:—

"Hates the day nurse, who is sceptical, and has no attacks in six days; has them after the night nurse comes on, who takes elaborate notes, which the patient is allowed to read.
"Has cataleptic spasms after having been told what the visiting physician expects of him.
"Conscious during temperatures of 117° and 132°.
"Pulse very irregular, while but slightly increased in frequency.
"Difficulty in passing urine.
"Loss of memory complained of.
"Frothing of mouth tinged with blood. Is stopped after he heard one nurse telling the other that such things were often done by biting the lips."

Dr. Jacobi puts down the high temperature as being caused by a paralysis of the inhibitory faculty of the heart centre It may be so, but we are still unconvinced.

THE LORD CHIEF JUSTICE ON LEGAL AND MEDICAL EDUCATION.

WE must leave to the authorities of the legal profession the responsibility of answering the serious charges made by the Lord Chief Justice against the present system of legal instruction. It certainly is a grave impeachment, coming from so high a quarter, and might be expected to take effect had not similar impeachments failed out of the mouths of still more weighty authorities in days past, such as Lord Westbury and Lord Selborne. Lord Russell was unsparing in his demonstration of the insufficiency of the present teaching, either in its theoretical or practical parts, and showed that a young gentleman with the aid of a "crammer" could go through all the needed legal education in eight months and become a fully fledged member of the Bar of England. His great demand is for a school of law which could be attached hereafter as a legal Faculty to a Teaching University in London whenever that much-needed institution shall emerge out of the chaos of our metropolitan educational condition. We notice two points in the Lord Chief Justice's speech. He not only insists on more thorough preliminary education and more careful systematic instruction in the principles of law, but insists, as authorities on medical education do, on good practical training. He says: "Nor will any system dispense with the need of practical study in the chambers of a working lawyer, which, however, may well (in the case of students for the Bar) be postponed to a later stage, and which, probably, may usefully occupy those earlier years of professional life when professional work is insufficient for full occupation." It is flattering to the medical profession, and especially to the General Medical Council, that the Lord Chief Justice finds in the development of medical education under the Council's influence an example and an argument for the guidance of the Inns of Court and other legal authorities in extricating themselves from inadequate and antiquated methods of teaching. His words are worth noting. "Indeed, the history of medical education in recent years, from the time when the College of Physicians and the College of Surgeons commanded the principal avenues to the profession to the changes wrought by the legislation of 1858 and 1886, affords an instructive example of the improvements that may be effected under a body such as the General Medical Council, clothed with public responsibility and broadly representative in its character."

UNION IN THE MEDICAL PROFESSION.

WE have constantly urged in these columns the need for greater union among members of our profession, and we are glad to see that our exhortations are followed in many parts of the world. We are led to make these remarks by the receipt of a paper read by Dr. Bayard before the Canadian Medical Association in August last. Concerning the club question, Dr. Bayard's remarks are so much to the point that we are tempted to quote them:—"A word about fees. I assume that each district has a code of fees, governed by custom or regulation. The competition is such that some may be induced to give their services for less than the minimum rate. This would be a grave mistake, for by so doing they proclaim that their services are not worth much, and their patients will naturally take them at their own valuation. The same may be said of the club doctor, who makes a trade of his profession and a slave of himself for a consideration that would be refused by the cab-driver who conveys him to his patient." These words are as applicable to the conditions which obtain here as they are to Canada, and a bond of union such as exists at Eastbourne and Bexhill is the only method of preventing the degradation of the hardest-worked and worst-paid profession in the world.

ARMY REORGANISATION.

WE have had the farewell order of the late Commander-in-Chief, and that of his successor on assuming the command of the army; and Lord Wolseley has since made an important speech at the Clothmakers' Company, in which he sounded the keynote of his future policy. We now await the issue of the Order in Council for an official declaration of how things are to stand as regards the duties of the Commander-in-Chief and the military members of the War Office staff. It will not, we think, be very difficult, after the speech of the War Minister at the Lord Mayor's banquet, to surmise what that Order in Council will most probably be. It goes without saying that the aim and object of Lord Wolseley, as announced by himself—namely, of putting the profession of arms on the same plane and platform as other professions, of making the army of the future a really effective fighting machine, and of selecting as far as possible the best and most highly qualified men to fill the various posts in it,—are principles and propositions which in the abstract commend themselves to the public mind. If the present Commander-in-Chief succeeds in applying those principles regardless of the interest of the privileged classes and of all party interests, and promotes men to various posts solely on account of their recognised ability and fitness for them, he will do an enormous amount of public good. That he will occasionally make mistakes is unavoidable, but these will inflict no permanent injury on his reputation so long as the general spirit and trend of his administration point in the right direction. It is abundantly clear

Digitized by Google

that His Royal Highness the Duke of Cambridge had the esteem of the army and was for many reasons very popular, but it is fully recognised that he only consulted his own dignity and the public interest in vacating the post he had so long held. The time had really come for a change and for a new order of things. Rumour is, naturally, full of the remodellings, reorganisations, and changes which are to take place, but these are of course mere conjectures. That the present Commander-in-Chief had a brother in the Army Medical Service, and that he had, and still has, a strong personal attachment to several members of that service, are pretty well known facts. We can only hope that if any changes are to take place in the medical service—and it seems to be anticipated that there will be—Lord Wolseley will strive to make it a really effective service for war and peace purposes alike, and that he will endeavour to act up to the principle he has enunciated with regard to all the other branches of the service. He seems to have a firm grasp of what was Lord Cardwell's intention in bringing about the present organisation and in attempting to weld together the whole of the land forces of this country into that mutual and harmonious action which must be an essential aim of any future organisation; he has, in addition to his own large personal experience, made a study of war in all its modern aspects and results, and has eminently the courage of his opinions. It now remains for him to give effect to his ideas with thorough integrity of purpose as regards the nation and the good of the army, and a keen sense of justice to all. He has set up a high standard for himself, and time will show how nearly he has reached or how far fallen short of it in the proud and prominent position that he now occupies.

THE TREATMENT OF ATRESIA VAGINÆ.

THE October number of the *American Journal of Obstetrics* contains an account by Dr. J. C. Webster of two interesting cases of atresia of the vagina, with some remarks on the treatment appropriate for this somewhat rare abnormality. In the first case there was an abdominal swelling felt reaching a little above the umbilicus; bimanual examination showed that the uterus was enlarged and only slightly movable, and that there was a cystic swelling, the size of the fœtal head, to the left of it. It was decided to perform abdominal section. The swelling to the left was then found to be the distended left Fallopian tube, somewhat extensively adherent to surrounding parts. It was removed as completely as possible with the corresponding ovary, and the uterine appendages on the right side were also removed. The patient did well for some weeks, and then died from septic peritonitis. At the post-mortem examination it was found that there was not complete absence of the vagina, but that the atresia involved the lower fourth of it only. In this case, although the uterus was over four inches long, there was no distension of the uterine cavity. In the second case the uterus was certainly distended, and reached to the umbilicus and was fixed. In this case Professor Simpson dissected through the atresic vagina to the uterus, and evacuated a quantity of dark, thick fluid. The patient did well, and menstruated twice after this operation. More than a year afterwards she returned with her old symptoms; it was found that the opening into the uterus had closed. Examination showed that the uterus was distended to the size of a cricket-ball, and that there was another cystic mass behind and to the left of it. The uterus was again aspirated, and diminished in size, but the other swelling remained the same. Some months later abdominal section was performed and the cystic mass partly excised. "The patient is now in the best of health." In this case there was complete atresia of the vagina, and the presence of a well-developed uterus in combination with this defect is noteworthy, as in such cases the uterus is generally rudimentary or absent. Dr. Webster considers that these cases go to show that *double operation* is the right treatment, that abdominal section with removal of the dilated tubes should first be performed, and that an operation for opening up the atresic vagina should be undertaken subsequently.

THE HEALTH OF HOP-PICKERS.

NOTWITHSTANDING the sultry weather of the late summer, the report of the medical officer of health of the Rye rural district (Dr. E. W. Skinner) on the health of the foreign hop-pickers during this season is most favourable. The picking commenced with the month of September and lasted about four weeks, the weather being bright and fine during the whole of the period. In eight parishes—Iden, Rye Foreign, Peasmarsh, Beckley, Northiam, Brede, Udimore, and Icklesham—temporary lodgings were found for some 1900 strangers, of whom 787 were children, a decrease of about 430 when compared with the influx of the previous season. They were variously lodged in permanent huts, vans, tents, and "lodges"—i.e., barns, stables, outhouses, &c., temporarily fitted up for the reception of the workpeople. There were 525 lodgings in all, each accommodating on an average rather less than four persons. "On the whole they were as comfortable, dry, and warm as could be expected. The water-supply in all cases was sufficient for their modest requirements, and of good quality." There was almost a total absence of sickness, Dr. Skinner reports, and not a single case of infectious disease. One infant died in a van from convulsions. Dr. Skinner adds, however, that while the authority's suggestion to place partitions in the various "lodges" was very generally adopted, in very few cases did another proposition—the provision of latrines and cooking shelters—receive any attention. He expresses a fear that, until these suggestions become by-laws, this will continue to be the case. The sanitary inspector's report was equally satisfactory.

THE ACTIVE AGENT IN SURGICAL PURULENT INFECTION.

MM. S. ARLOING and EDOUARD CHANTRE in 1893 published a note in the *Comptes rendus de l'Académie des Sciences*, in which they stated they were in accord with the observations of Heiberg, Baumgarten, Cornil and Babes, and others establishing experimentally that surgical purulent infection, now of extremely rare occurrence, can be produced by the ordinary pyogenic agents, to the exclusion of all septic microbes. In the case observed by them the infectious agent was the streptococcus pyogenes. They have now sought the cause which occasions this microbe to leave its primary focus, where it so often remains quiescent, and disseminate itself through the system to form metastatic abscesses. Their experiments have satisfied them that without formally excluding the influence of the organism of the patient, the streptococcus owes its invading power to a particular state of virulence into which it may pass. This state is the same as that which it presents in puerperal septicæmia, and not that in simple phlegmon or erysipelas. A series of comparative inoculations on the guinea-pig and rabbit made in different ways has enabled them to formulate the following conclusions. The essential agent of purulent surgical infection is one of the ordinary microbes of suppuration, and is, in the case observed by them, the streptococcus. If other microbes are frequently found in the lesions they may complicate the purulent infection, but they are not necessary to its development. To produce purulent infection the streptococcus must acquire the virulence that it possesses in the acute and grave forms of puerperal septicæmia, and not that which it exhibits in erysipelas or simple phlegmon. There exist close etiological relations between surgical purulent

Digitized by Google

infection, puerperal septicæmia, and erysipelas, but we are still ignorant of the place and the mode in which the streptococcus acquires the pathogenic properties which cause it to produce the one or the other of these several states. They find that the micrococci have a disposition to form bacilli in conditions still unknown or badly determined either within or without the organism. The virulence of the bacilli is liable to the same variations as that of the streptococcus. Lastly, it is not necessary to conclude that there is a mixture of a pyogenic agent with a foreign microbe when bacilli are found commingled with streptococci, for the bacilli may only be modified streptococci.

THE USE OF DRUGS.

ADDRESSES before medical societies usually lean in one of three directions—the literary, the speculative, or in the direction of comparison of the past with the present and the future. The practical side is but seldom treated in these formal addresses. As will be seen by a letter which we publish elsewhere, the Willesden and District Medical Society determined—as an outcome of an address by Dr. Gowers on the Use of Drugs—that there should be a discussion on the question—"What drugs are considered most useful in general practice?" Every member of the association was asked to send in a list, and from this list the following drugs have been selected—iodide of potassium, antipyrin, liquor arsenicalis, tinctura digitalis, and liquor strychniæ. We trust that calomel and opium are so universally considered useful as to be without the pale of discussion, otherwise their omission seems strange. Collective investigations of this kind ought to give rise to valuable results, and we congratulate Dr. Gowers—whose address we shall publish shortly—on his having been the means of initiating such investigation by a local society.

PULMONARY ACTINOMYCOSIS IN A SHEEP.

HITHERTO instances of actinomycosis in the ovine species have been rarely, if ever, recorded, the animals in which it has been commonly observed being those of the ox tribe and sometimes the horse. In a recent issue of the *Zeitschrift für Fleisch- und Milchhygiene* Herr Gripps, veterinary surgeon at Stettin, gives the description of a sheep which was killed at the abattoir of that town, and in which the whole of the anterior moiety of the left lung was transformed into a hard, dense mass, nodulated on the surface, and varying in tint from a greyish blue to a dirty yellow or grey. On the surface and also on section there were somewhat brighter-coloured granules, the largest of which were about the size of a hempseed. The bronchial lymphatic glands, as well as those in the mediastinum, appeared to be free from these minute bodies. These, when examined by means of the microscope, were found to be composed of masses of small cells of various dimensions in a stroma of wide-meshed connective tissue. The centre of these masses was occupied by clusters of actinomycetes, large and small; some of the largest were surrounded by a zone of epithelioid and giant cells. The case, apart from its rarity, is very interesting.

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

AT the last meeting of the Board Mr. Sharp presented the annual report of the School Attendance Committee, which dealt with, among other matters, the question of medical certificates. First of all, let it be clearly understood that by a pious fiction the School Board never asks for, or even wants, a medical certificate; that attack upon the liberty of the subject is the work of the wicked and hard-hearted magistrate, but the Board, not being able to trust ordinary medical men, has appointed its own, to help the magistrates. We may remind our readers that not so very long ago it tried hard to get its own magistrates, too, the ordinary magistrate not being good enough. The report of the School Attendance Committee is somewhat querulous: 1. Sometimes there was no medical certificate at all. 2. Sometimes the certificate simply stated that the child was "ill." In our opinion there is no reason why the certificate should state anything more. The Board would not know the meaning, say, of "tuberculous meningitis" unless it condescended to ask its own medical officer, whose opinion it has ignored all through this controversy, and, besides, the illness of a child is a confidential matter between the parents and the medical man. 3. Sometimes children thus certified had been found playing in the streets or at work. The Board, of course, does not know that in some illnesses—chorea, for example—playing is not harmful, when going to school would be. 4. The committee could not understand why the action of the Board had been objected to, but the objectors had probably been instigated by others. We are sorry that we do not seem to have made ourselves clear, but we refer the committee to our issues of June 8th, July 6th and 20th, and Aug. 3rd of the current year. Medical men—and even a medical man has feelings—do not like the cases in which their certificates are "considered by the divisional superintendent to be doubtful"[1] examined by other medical men behind their backs. That is all.

INTERNECINE LITIGATION.

AT the Manchester assizes on Nov. 6th the case of Brooks *v.* Eatough came before Mr. Justice Collins and a special jury. The parties were members of a firm of medical practitioners in Mossley, and the plaintiff sued the defendant for slander in that he (the defendant) had gone to a lady patient of the plaintiff and made statements to her, in the presence of another lady, reflecting on his professional skill and moral reputation in his treatment of the said lady. We need not give any details, but we may say that the lady in question gave evidence as to the defendant's statement to her, and also said that he had asked her to give evidence against the plaintiff, but that she declined. Eventually the jury found a verdict for the plaintiff, with £300 damages. The action, it appears, was only taken after unsuccessful efforts had been made to dissolve the partnership, and we may remark that it is a great pity for professional men of any sort to carry private quarrels into a public court, although perhaps in this case there was no other way out of a difficult position. A case of this kind is a sort of nine days' wonder. All the details are seized upon and gloated over by prurient minds, and a great deal of scandal is thereby caused. It is a matter for congratulation, however, that the medical profession is, as a rule, singularly free from scandals of this kind, and long may it be so.

ARTERIO-VENOUS ANASTOMOSES.

M. G. GÉRARD of Lille, in an article which appeared in the *Bulletins de la Société de Biologie* of Paris (No. 1) at the beginning of the present year, announced that he, with M. Ch. Debierre, had discovered an anastomosing vessel passing directly from the external iliac artery to the external iliac vein. Since that date he has continued his investigation in the adult and in infants by means of general and local injections, by dissection, and by microscopic examination, and has communicated the result at which he has arrived in the October number of the *Archives de Physiologie*. He has arrived at the conviction that there exist in many parts of the body communicating vessels between arteries and veins which may be easily followed and dissected. Such anastomoses are

[1] Mr. Sharp's answer to Mr. A. Riley, June 27th, 1895.

Digitized by Google

particularly common at the points of flexion of the joints—such, for example, as at the axilla, elbow, groin, and popliteal region. In infants the anastomoses were most common in the following order of frequency in fourteen subjects: groin, 5; popliteal space, 4; axilla, 3; elbow, 3; and between the aorta and vena cava, 1. In adults he had only the opportunity of examining nine subjects, in whom he found four anastomoses, all situated in the lower limbs. In the majority of cases the anastomosis was directed from the vein to the artery, running from above downwards. He was unable to discover any intra-muscular anastomoses, though he took much pains in searching for them. The length of the anastomosing vessel varied from 4 mm. to 45 mm., the average length being from 15 mm. to 30 mm. In infants the vessel is infundibuliform at the points where it opens into the artery and vein, and is narrowest near the middle of its course. In adults it is nearly uniformly cylindrical, and the walls are very thick. The calibre of the vessel varies according to its state of repletion from 0·4 mm. to 3 mm. From a physiological point of view M. Gérard regards these vessels as belonging to the nutritive circulation of Claude Bernard, but in addition considers that they fulfil a certain *rôle* in regulating variations of tension and pressure.

DUBLIN UNIVERSITY PARLIAMENTARY ELECTION.

PROFESSOR WINDLE, Dean of the Medical Faculty of Mason College, Birmingham, having written as an elector to Mr. Lecky, now a candidate for the University representation, calling his attention to certain points in connexion with the medical profession, has received the following reply:—

"It would be very unpardonable of me if I did not take a deep interest in the Irish Medical School, for there is certainly no other profession in Ireland which has produced during the present century so many men who have justly won a European reputation, and it is, I am afraid, only too true that a profession which cannot appear prominently on platforms or in Parliament is apt to be neglected by politicians. Should I be elected to Parliament I would consider it to be my duty to look carefully into any grievance under which Irish doctors may suffer, and to use any influence my position might give me to have them redressed. The regulations of English hospitals are, of course, not within the cognizance of Parliament. As to any disabilities or disadvantages under which Irish doctors suffer and from which English doctors are exempt, they ought, if possible, to be remedied. I should be glad if I could do anything to further the work. I may also add that I will do everything in my power to support any measure which may have the effect of improving the condition of the Irish Poor-law medical officers, and I shall also use every effort to have any legitimate grounds of dissatisfaction with present arrangements which may exist amongst the members of the Army Medical Staff removed."

We never interfere in politics from a party point of view, but as we have similar things to say in this case of each candidate, we have no hesitation in commending Mr. Lecky's attitude to the favourable notice of a large body of his constituents—viz., the medical electorate, for there is about these words a ring of sincerity differentiating them from mere electoral promises. Mr. Lecky appears to understand the hardships he is asked to pledge himself to attempt to redress, while his words that "a profession which cannot appear prominently on platforms or in Parliament" runs a risk of being neglected by politicians come home to us closely, for we know them so well to be true. Mr. Wright, Q.C., has expressed himself in similar terms to a constituent, so that we may congratulate the medical graduates of the University on the fact that they cannot choose the wrong man.

THE annual dinner of the staff and past and present students of the Dental Hospital of London will be held on Saturday, Nov. 30th, at the Café Royal, under the presidency of Mr. Frederick Canton. Gentlemen either now or formerly connected with the hospital or medical school who may, through inadvertence, not have received special notice, and who desire to be present, are requested to communicate with the Dean, at the Dental Hospital, 40, Leicester-square, W.C.

DR. PATRICK MANSON will take the chair at the November dinner of the Aberdeen University Club, London, which will take place on the 20th inst., at 6.45 P.M., in the Holborn Restaurant. Members intending to be present at the dinner should communicate with the honorary secretaries, Mr. J. Gerard Laing, 1, Elm-court, Temple, E.C.; and Dr. James Galloway, 21, Queen Anne-street, W.

THE opening by the Duke of Devonshire of the new Home built by Mr. Passmore Edwards at the colony of the National Society for the Employment of Epileptics at Chalfont St. Peters, which was postponed from Aug. 7th last owing to his Grace being summoned to Osborne on that day, has now been fixed to take place on the 26th inst. at 2.45 P.M.

THE Edinburgh University Club held its quarterly dinner on Wednesday, Nov. 13th, at the Holborn Restaurant; Mr. W. Watson Cheyne, F.R.S., was in the chair. Among the guests were the President of the Royal College of Surgeons of England (Mr. Christopher Heath) and Mr Yarrow.

PROFESSOR CURNOW, M.D., will resign the office of Dean of the Faculty of Medicine of King's College, London, at the end of the present year, after twelve years' service, and will be succeeded by Sir Hugh Beevor, Bart., M.D.

THE ASHANTI EXPEDITION.

IT is a somewhat singular and lucky coincidence that the accession of Lord Wolseley to his present appointment as military head of the army should have occurred at the time when an expedition to Ashanti was about to take place. The Commander-in-Chief and the headquarters staff have been busily engaged of late upon the plans for the operations from the African West Coast against Ashanti, and great activity prevails at the Government manufacturing and supply departments. Sir Francis Scott, having made all his arrangements with the War Office in this country, will, it is understood, leave for Accra on the 22nd inst. The contingent of British troops from this country have received their orders, but the number of these will be very considerably less than it was in the last expedition in 1873–74 under Sir Garnet Wolseley. The force of European officers and men was then over 2500, whereas it is reported that on this occasion the British troops sent from this country will be under 300 at present. With this addition, there is, it is believed, a sufficient force of seasoned troops already present on the spot or on the West Coast of Africa, in the West India regiments and the Houssas, for the work of the campaign. The view entertained locally on the West Coast, however, appears to be that we are in this country rather underrating the strength of the force necessary for the coming expedition. Be this as it may, reliance may be safely placed upon the results of our previous experience and that of Lord Wolseley and Sir Francis Scott, who possess a thorough knowledge of the country and of the different nature and increased efficiency of the weapons that are now employed in warfare. Whatever may be the losses from wounds and injuries received in the forthcoming campaign, we may safely assume that there must be a certain amount, and possibly a large amount, of inefficiency and sickness from malaria and climatic causes. The low-lying country between the coast and the highlands is difficult and unhealthy; but the amount of sickness to be anticipated very greatly depends upon the selection of the best season for the march to Kumassie, the nature of the supplies, the adequacy of the transport, and the foresight that is exercised generally in providing for the troops. In all these respects the authorities may be safely guided by the results of their previous experience. The rainy season is very unhealthy. The healthy season is the dry one from December to March, when an

Digitized by Google

expedition can be undertaken with considerably less risk to health, with far greater facilities, and better prospects of success than during the rains. The mortality of the force which marched to Kumassie under Sir Garnet Wolseley from disease and loss in action was only 3·14 per cent. of the strength disembarked. On the present occasion the force will almost entirely consist of acclimatised troops; the European portion of it will be composed of matured soldiers and seamen from the Royal Navy; the ammunition and supplies will be provided and packed with a view to facility of transport; and the march will be undertaken at the end of the rainy season. Special attention having, no doubt, been paid to the exceptional circumstances of the expedition, and all that foresight can do having probably been done, we may now confidently hope to reap the results of the precautions taken.

HOUSE PROPERTY IN ISLINGTON AND THE VESTRY OF ST. MARY, ISLINGTON.

WE have received from Mr. A. E. Harris, the medical officer of health for Islington, a copy of a communication which has been sent to every member of the Islington Vestry by Mr. E. Edwards, secretary of the Metropolitan House Investment and Agency Company, Limited, and also a copy of a letter which he (Mr. Harris) has addressed to the Secretary of the Local Government Board. The letters are as follows:—

I.

[COPY.]

The Metropolitan House Investment and Agency Company, Limited,
16, Eastcheap, London, E.C.,
5th November, 1895.

Dear Sir,—I wish to draw your attention to the enormous expense and loss which is being occasioned to owners of house property in the parish of St. Mary, Islington, by the manner in which the sanitary department of your vestry are at the present time enforcing the powers conferred upon them by the Public Health Acts.

I will preface my remarks by informing you that this company owns 68 houses in the parish, and collects the rent of 51 other houses, as agent for the respective owners, making a total of 119 houses of the aggregate net annual ratable value of £3500 or thereabouts, and representing an invested capital of £40,000. If so requested, I will in confidence give the addresses of all the houses to any member of the vestry, but for obvious reasons I do not care to furnish this information in this letter. All the houses are in excellent repair and are let to most respectable tenants, the rentals averaging from £32 to £50 per annum. They are all situated in good streets, and, with the exception of nine houses (all in one street), none are let to weekly tenants. During the period from Jan. 1st, 1894, to the present time notices have been served by your sanitary department on no less than fifty-three of the above-mentioned houses, necessitating in all but two or three cases the entire relaying of the drains and erection of ventilation shafts &c. As you are no doubt aware, the minimum cost of complying with these notices is £30 per house, and where there are two waterclosets £35. I have, therefore, expended on sanitary works alone in such fifty-three houses upwards of £1600 in a period of one year and nine months, quite exclusive of the usual expenditure for decorative and structural repairs. The effect of this expenditure means that if the company's estate was confined to the parish of Islington it would have been impossible to have paid our investors any interest on their capital during the past two years. I need not remind you that this continuous outlay renders house property in your parish almost worthless, as you can see for yourself by perusing the results of sales, or attempted sales, of Islington houses at the auction mart.

I do not suppose that the property of this company has been singled out for attack, but it is an extraordinary thing that wherever this company owns or manages a house a notice is sure to be served sooner or later, whilst, so far as I have been able to ascertain, adjoining houses are seldom treated in the same manner. For instance, in New North-road the only four houses in which the company is interested have all been entirely redrained under the orders of your vestry, whilst only one other house in the same block (about forty in number) appears to have been served in the same way; and the same thing occurs in Stavordale-road, where only two houses are owned, but upon both of which notices have been served. That this proportion of notices to number of houses is the usual thing seems incredible, but if it be so your medical officer and his staff evidently have in view the entire reconstruction of all private drains in the parish. If the vestry are with Dr. Harris in this, it would surely be more honest and straightforward to make an order for the testing of all private drains and for reconstruction of all that prove defective. Owners would then know what to expect, and could make their arrangements accordingly. I would remind you that to do this throughout the parish would involve the outlay of some millions of money. I also find that in cases where (under the recent decisions of the judges) the onus of reconstructing the drains is thrown upon the vestry, every effort is made to compel the individual owner to do the work, and should he, in ignorance of the law, carry out the same, your vestry have refused to refund any portion of the expense. I allude particularly to the drainage of Nos. 47, 49, 51, 53, and 55, Queen's Head-street, and 13A and 14A, John-street, reconstructed by me at a cost of over £100.

Owing to the frequency with which these notices have been served upon the company's property, my directors some time since resolved that no more houses should be purchased in your parish, and notwithstanding the fact that this company has since purchased £50,000 worth of property in London, not a single house has been bought in Islington, and this policy will be continued until the present arbitrary enforcement of your vestry's powers is very considerably modified. Several of the largest buyers of house property in London are associated with the company in this decision. The company own over 300 houses in other metropolitan parishes, and the proportion of notices served in those parishes does not amount to 3 per cent. per annum on the number of houses owned.

I am sending a copy of this letter to each member of the vestry, to the vestry clerk, and to the *Islington Gazette* for publication.

Yours truly,
(Signed) ERNEST EDWARDS, Secretary.

II.

[COPY.]

The Vestry of St. Mary, Islington.
Vestry Hall, Upper-street, N.,
7th November, 1895.

The Secretary, Local Government Board,
Whitehall, S.W.

SIR,—Herewith I beg to forward you a copy of a circular letter which has been addressed to every member of the Vestry of St. Mary, Islington, which authority I have the honour to serve as its medical officer of health, by the secretary of the Metropolitan House Investment Company.

The letter has been sent, I have no doubt, with the object of deterring me from discharging my duty to this parish, and with a hope that it might bring me into trouble and difficulty with my authority. I need hardly say that it will not have the first-mentioned effect, whatever it may have with respect to the latter, because, being placed in a position of comparative independence by Section 108 (c) of the Public Health (London) Act, 1891, I shall fearlessly continue to perform my duties in a manner consonant to the regulations laid down by the Local Government Board for my guidance.

My chief object in forwarding you this document is to place before you a very strong argument why medical officers of health should be appointed to their positions, to use the words of the above-mentioned Act, "not for a time only." If such a practice as that adopted by this company were to become universal a new terror would be imported into the lives of all medical officers of health who are periodically elected to their positions; for naturally they would be more or less timorous in zealously performing their duties, having before their eyes the troubles which such a document as the enclosed is calculated to entail on them.

I might say, as regards the note itself, that the writer is very careful to avoid libelling either myself or any member of my staff, and also he omits to state, although cognisant of the facts, that in every instance the premises were visited either by reason of the occurrence of an infectious disease or through complaint having been made to me of their insanitary condition.

I am, Sir, your obedient servant,
(Signed) ALFRED E. HARRIS,
Medical Officer of Health.

We have commented upon these letters in a leading article, and agree with Mr. Harris that the life of the medical officer of health would become terrible if such methods were often employed against him when engaged in the honest discharge of his duties.

THE BACTERIOLOGICAL EFFICIENCY OF FILTERS.

IT is well known that bacteriology has introduced a means of discrimination between filters which are worse than useless and those which may be depended upon to offer an effective resistance to the passage of pathogenic organisms. The test is severe, but not unreasonably so when it is considered what may be the results of employing a filter for domestic purposes which does not possess this high degree of filtering efficiency. In this connexion the following report, sent to us by Dr. Klein, upon the bacteriological efficiency of the Silicated Carbon Pressure Needle Filter, of which we took a favourable view in a notice which appeared in our issue of July 21st, 1894, is of interest.

The testing was in all cases carried out in the following manner:—The filter as a whole (with metal case) was, for each operation, sterilised in the autoclave at a temperature of 120° C. for thirty minutes; it was then allowed to cool. By means of a sterilised india-rubber plug it was fixed in an upright position in the mouth of a sterile flask, which, for the object of air exhaustion by means of a pump, was provided with a lateral opening. From a fresh, active culture of the various microbes presently to be mentioned, grown on the surface of solid medium (agar or gelatine, as the case may be), a small particle was taken and distributed in 100 c.c. of boiled, and then cooled, distilled water contained in a sterile flask. By shaking the water a complete and uniform distribution of the microbes in the water was effected. By means of plate

Digitized by Google

cultivation the number of microbes in this distribution was ascertained prior to subjecting it to the filter; in all cases five cubic millimetres, or $\frac{1}{200}$ cubic centimetre, were used for each plate, and after incubation the number of microbes was counted. The remainder of the distribution was pumped through the filter, and of the filtrate 250 cubic millimetres (or $\frac{1}{4}$ cubic centimetre) were used for each plate; this was then incubated and the result watched.

Proceeding in this way the following results were obtained:—

1. *Filtration of a distribution of bacillus prodigiosus.*—This microbe was chosen on account of the easy detection of the colonies by their bright crimson colour. The number of microbes in the distribution ascertained by agar plates was 44,800 per 1 c.c. The agar plate made with $\frac{1}{4}$ c.c. of the filtrate produced no colonies.

2. *Filtration of a distribution of staphylococcus aureus.*—This microbe is also easily recognised in agar plates by the bright-yellow colour of its colonies. The number of microbes in the distribution ascertained by agar plates was 56,600 per 1 c.c. The agar plate made with $\frac{1}{4}$ c.c. of the filtrate produced no colonies.

3. *Filtration of a distribution of spores of bacillus anthracis.*—The colonies of bacillus anthracis are easily identified. The number of spores in the distribution ascertained by gelatine plates was 32,000 per 1 c.c. The gelatine plate made with $\frac{1}{4}$ c.c. of the filtrate produced no colonies.

4. *Filtration of a distribution of bacillus of typhoid fever.*—This bacillus is also easily identified. The number of microbes in the distribution ascertained by gelatine plates was 151,000 per 1 c.c. The gelatine plate made with $\frac{1}{4}$ c.c. of the filtrate produced no colonies.

5. *Filtration of a distribution of vibrio of cholera.*—This is also easily identified. The number of microbes in the distribution ascertained by gelatine plates was over 126,000 per 1 c.c. The gelatine plate made with $\frac{1}{4}$ c.c. of the filtrate produced no colonies.

6. *Filtration of a sample of drinking-water.*—This water had been submitted to Dr. Klein for bacterioscopic examination, in order to ascertain whether it could be recommended for drinking purposes. The number of microbes present in the water, ascertained by gelatine plates, was 30,416 per 1 c.c. Gelatine plates made with $\frac{1}{4}$ c.c. of the filtrate produced no colonies.

Conclusions.—It follows, then, from these experiments that of the distributions of the various microbes in sterile distilled water in no case did any of the microbes pass the filter. It will be noticed also that, although the number of microbes present in the water prior to filtration was very large, and although as much as $\frac{1}{4}$ c.c. of the filtrate was used per plate, in no single instance was any growth produced from this latter, the filtrate being absolutely sterile. These results justify the conclusion that the filter completely removes microbes from water, and is therefore absolutely reliable.

Tabular Statement of Results.

Nature of the fluid.	Number of microbes prior to filtration.	Number of microbes in the filtrate.
A. Bacillus prodigiosus in distilled water	44,800 per 1 c.c.	None.
B. Staphylococcus aureus in distilled water	56,600 per 1 c.c.	None.
C. Spores of bacillus anthracis in distilled water	32,000 per 1 c.c.	None.
D. Typhoid fever bacillus in distilled water	151,000 per 1 c.c.	None.
E. Cholera vibrio in distilled water	over 126,000 per 1 c.c.	None.
F. Drinking-water	30,416 per 1 c.c.	None.

LITERARY INTELLIGENCE.—Mr. H. K. Lewis will shortly issue in his "Practical Series" "The Treatment of Pulmonary Consumption, a Practical Manual," by Dr. V. D. Harris and E. C. Beale.—"Science for All," a cyclopædia of popular science, written by eminent men in simple language, profusely illustrated, and edited by the late Dr. Robert Brown, has hitherto been issued in five volumes at 9*s.* each, but in order to bring it within universal reach Messrs. Cassell and Company have arranged to publish it in twenty monthly parts at 6*d.* The first part will be published on Nov. 26th.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE Council of the Metropolitan Hospital Sunday Fund met in the saloon of the London Mansion House on Thursday, Nov. 7th, to receive a second report from the Distribution Committee of the Fund. Sir JOSEPH RENALS, Bart., the ex-Lord Mayor, presided.

Since the awards for the year 1895 were made additional subscriptions amounting to £16,000 have been placed in the hands of the Lord Mayor, and the Council were asked at the present meeting to sanction the distribution of the extra sum among the various hospitals and dispensaries that participated in the previous distribution, 5 per cent. of the total amount to be, as usual, reserved for the purchase of surgical appliances.

The minutes of the previous meeting having been read,

Dr. GLOVER (who gave notice at the last meeting of the Council that he intended to move for the appointment of a sub-committee to investigate the statistics of the out-patient departments at the various hospitals) said it would be scarcely fair to ask this Council, which had nearly come to the end of its year of existence, to go into the question of out-patients. He therefore asked leave to postpone the matter till another meeting. This was granted.

Sir SYDNEY WATERLOW, in rising to propose the adoption of the Committee's report, said it was very gratifying to him, and he was sure they would all sympathise with him as chairman of the Distribution Committee, that the funds placed in the hands of the Lord Mayor made it necessary to call another meeting of the Council for the purpose of confirming a second report. This was the twenty-third year that a collection had been made, and never had a collection approached the sum that had been reached this year. They had always been struggling to reach £50,000, and now, owing to the energy of a large number of gentlemen, they were able to announce a collection of over £61,000. Immediately he learned that a further sum had been placed in the hands of the Lord Mayor he called a meeting of the Committee of Distribution, because the principle upon which the Fund had always been administered was to give the benefit of the money collected in the year to the sick poor of the metropolis without delay, and not to put any by. They had already distributed £45,000, and it was proposed to ask this meeting to confirm the second report, which recommended that a further sum of £15,850 should be divided amongst the several hospitals as set forth in the schedule. Before closing his remarks he wished to say that part of the proceedings of the Committee of Distribution had not been entered upon the report. The Committee felt that they ought to express to Mr. Burdett their best thanks, and he hoped that the Council would include those thanks in any resolution they might pass to-day. It should also not be forgotten that the funds collected this year had been greatly increased by the very deep interest that the Lord Mayor had taken in the Fund ever since he had been in office, and he was sure that Sir Joseph Renals felt quite as strong a feeling of gratitude that the public had recognised so largely his efforts to increase the Fund. He, therefore, begged to move that the second report of the Distribution Committee be approved.

Lord KNUTSFORD, in seconding the resolution, which was unanimously agreed to, heartily concurred in all that Sir Sidney Waterlow had said.

His Eminence Cardinal VAUGHAN then proposed for the Council's adoption a series of resolutions passed by the Committee of Distribution thanking Mr. Burdett for the great interest he had taken in the Fund for many years past, and especially for obtaining subscriptions raising the present collection to the unprecedented sum of over £60,000; Mr. B. I. Barnato, Daniel Marks, and friends for their handsome and generous contribution of £10,000; and Messrs. Burdett and Harris and Messrs. Pym, Vaughan and Company for obtaining £3400 from members of the Stock Exchange. He did not ask them to merely confirm these resolutions, but to adopt them as their own. He felt that it needed no words of his to commend these resolutions to the acceptance of the meeting. Inasmuch as they were all deeply interested in the great work of ministering to the corporal necessities and wants of the poor in this great metropolis, they must feel all the deeper gratitude to these gentlemen who had helped to raise the sum for hospital

Digitized by Google

distribution to the large amount recorded. They were bound to record their high appreciation of the time, influence, and money which had been placed at their disposal by these gentlemen for the benefit of the poor so that the general public might understand how such services are appreciated, and he called upon all to imitate the noble example set before them.

Mr. R. B. MARTIN, M.P., seconding the motion, thought that a vote of thanks ought particularly to be passed by this Council because not only had the gift of money raised the income of the Fund, but it showed what an enormous amount of good could be done by individual efforts. These gentlemen had worked among their own circle of friends, and he thought the Council could not do less than record their names.

The motion having been heartily agreed to,

Mr. H. C. BURDETT said that it would be wrong for him not to acknowledge that the work he had done this year had been performed at considerable personal cost both of energy and time; but he felt that, however natural and however proper it might be for them to desire to personally thank him, still, the less the individual was brought forward on this occasion the better. There was no way they could help the hospitals better than by showing what a measure of success the Fund could obtain. The unit of confidence was the Committee of Distribution; had it not been for them it would certainly have been quite impossible to raise the amount of money which they had raised this year. There were people who criticised the methods of distribution—and he himself in early years was among the number of the critics, but as he had grown older he had come to the conclusion that it would pass the wit of man to devise a scheme that would not lay itself open to the criticism of somebody. Knowing that the members of the Committee are independent and not connected with any hospital, he thought he might say that they owed an immense debt to the Committee, and that there was every confidence to be placed in their methods. Sir Sydney Waterlow was the acting spirit and head of the Committee, and it was only right to regard that Committee as the platform from which it had been possible to raise the fund to £61,500. With reference to the question of personal services, eight good friends, one of them a member of the Council—he had been forbidden to mention names—felt that they might have a little syndicate in the cause of charity amongst themselves, and he wished the point to be remembered that in thanking him the Council were thanking those friends. The resolution covered all those who had helped to raise the money. The figures representing the congregational collections showed an increase approaching £5000, and there was a deep debt owing to the clergy and ministers of all denominations. It would be invidious to single out names, but it was impossible to forget the special services which the Archdeacon of London had rendered this year, nor could they forget the Archbishop of Canterbury, the Dean of Westminster, the Chief Rabbi, Canon Fleming, and Dr. Ridgeway. There were a great number of people who, desiring to help hospitals, felt some difficulty in deciding what hospital to give to, and the Hospital Sunday Fund afforded a means to these people of placing the money in the hands of the Lord Mayor, knowing that it would be distributed among the hospitals according to their respective needs and merits. On this occasion he could not omit to mention the personal services of the present Lord Mayor, and he doubted very much the possibility of raising the money had it not been for him. The Lord Mayor's secretary, too (Mr. Soulsby), had taken a great amount of trouble on behalf of the Fund, and had also devoted a great amount of time to it. There had been several individual donations of £1000. The Stock Exchange list included some 400 individuals and Mr. Barnato's list some 500. From £27,000 the total annual receipts of the Fund had gone up to £61,500, and he believed that that sum would never decrease. It was not an impossible conception that in the future the sum reached might be £100,000; it was a very hopeful conception, and he thought that the encouragement they had received this year proved that he could express reasonable confidence in this view. It was to one man more than to any other, he believed, that they owed Hospital Sunday in London. He alluded to the late Dr. James Wakley (whose work had since been taken up by his brother, Mr. Thomas Wakley, to whom they were all so much indebted), and the success they had attained would be a measure of great satisfaction to him if he could know it.

Mr. BURDETT then proposed a resolution to the effect that the cordial thanks of the Council be conveyed to the Press on behalf of the medical charities of London for the special support that they have so cordially rendered in raising the fund to the magnificent and unprecedented total this year; and that a copy of the resolution signed by the Lord Mayor be sent to the editors of all papers. They owed much of their success to the press. Had it not been for the kindness of the proprietors of the *Graphic* in placing their artist at his disposal it would have been impossible for him to have brought out the special number of the *Hospital* with illustrations. Then again there was Mr. Arthur Walter of the *Times*, who, setting aside all precedents, gave way on a point in the interests of the Hospital Sunday Fund which he had never given way on before by admitting blocks into the columns facing the leaders. He thought it was right he should mention this fact because it was a very material contribution towards the results which had been attained. All the other editors had rendered material support, and, passing by his own paper, he could not sit down without specially thanking, and asking the Council to thank, THE LANCET. It had devoted to the cause of Hospital Sunday an amount of space which he knew must have cost several hundred pounds, and it was to THE LANCET that this year they owed a special Hospital Sunday Supplement which was circulated throughout the churches, and of which 125,000 copies were printed for gratuitous distribution. He asked the Council to pass this resolution, not in a formal manner, but in a manner which they knew was vital to their interests.

Mr. HOSKIER seconded, and the vote was heartily accorded.

The CHIEF RABBI proposed that the cordial thanks of the Council be given to the Right Hon. Sir Joseph Renals, Bart. for his efforts in making the present year a record year of the Fund.

Canon FLEMING seconded, and the motion was unanimously carried.

The LORD MAYOR, in acknowledging the vote, said it was quite in the true fitness of things that almost the last meeting at which he should preside in this Mansion House should be one so deserving of the sympathy of every Englishman as the Hospital Sunday Fund. They all believed that this fund was gradually growing upon the public and he hoped that ultimately even the figures suggested by his friend Mr. Burdett might be increased. If in the years to come he could help the fund in his small way he should be only too happy to do so, and among the pleasant memories of the Civic Chair that he should leave behind him none would be more pleasant than the fact that during his year of office the the Metropolitan Hospital Sunday Fund had risen to an amount it had never done before.

The proceedings then terminated.

There were present: The Right Honourable Sir Joseph Renals (President and Treasurer) Sir Sydney H. Waterlow (Vice-President), his Eminence Cardinal Vaughan, D.D., the Very Rev. Chief Rabbi Dr. H. Adler, the Venerable W. M. Sinclair, D.D. (Archdeacon of London), Rev. Canon Fleming, B.D., Rev. J. Monro Gibson, D.D., Rev. Dr. Marks, Rev. S. B. Burnaby, M.A., Rev. Andrew Crombie, Rev. C. H. Grundy, M.A., Rev. W. H. Harwood, Rev. E. E. Jenkins, D.D., the Right Hon. Lord Knutsford, G.C.M.G., Sir George B. Bruce, Sir Richmond Cotton, Mr. R. B. D. Acland, Mr. Henry C. Burdett, Mr. Thomas Christy, F.L.S., Mr. Alfred L. Cohen, Dr. J. G. Glover, Mr. J. H. Hale, Dr. C. J. Hare, Mr. Albert G. Sandeman, Mr. Wakley, F.R.C.S., Mr. H. Cosmo O. Bonsor, M.P., Mr. James Cundy, Mr. Herman Hoskier, Mr. Richard B. Martin, M.P. (Honorary Secretary), and Mr. Henry N. Custance (Secretary).

Letters of apology for absence were read from: Sir Edmund Hay Currie, Mr. Thomas Bryant, Captain Palliser, Mr. Howard Potter, the Bishop of London, Canon Ingram, Sir Savile Crossley, Mr. John Mackerel, Rev. C. J. Ridgeway, Lord Charles Bruce, Mr. Carr-Gomm, Mr. Richard Foster, Mr. Alfred Willett, Dr. Munro Gibson, and others.

THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE autumn meeting of this association was held in the International Hall of the Café Monico on Tuesday, the 12th inst., and was followed at 7 P.M. by the annual dinner. The President, Dr. Phillips-Conn, was in the chair, supported by

Digitized by Google

one of the largest gatherings in the history of the association. The guests were numerous and included the Lord Chief Justice of England, Mr. Justice Mathew, Lord Battersea, the Bishop of Newport and Menevia, Sir F. Osborne, Mr. Yarrow, Dr. Nicolson (medical superintendent of Broadmoor), Dr. Frederick Roberts, Mr. Thomas Smith, Dr. Stephen Mackenzie, the Rev. Dr. Gwynne, Dr. Robert Anderson, Captain Whiffin, R.M.A., Mr. W. H. Battle, and Mr. Percy B. Dunn.

The Association will thus be seen to have fully maintained its character for hospitality. Sir Walter Foster, M.P., proposed "The Guests," and the Lord Chief Justice of England replied. "The Association" was proposed by Mr. Justice Mathew in an able and amusing speech, which was responded to by the President of the Association. "The Services" was proposed by Dr. Richard Heath, who referred to the position which Irishmen held in the Army at the present time, and Inspector-General W. H. Lloyd, R.N., replied for the Navy. "The Learned Professions" was proposed by Dr. A. Macalister, F.R.S., Professor of Anatomy in the University of Cambridge, who pointed out the important posts now held in these professions by Irishmen resident in this country as a proof that it was possible for them to attain the very highest appointments if they had only the necessary ability. Responses were made by the Bishop of Newport and Menevia, Mr. Charles Cagney and Dr. Frederick Roberts. The Lord Chief Justice proposed the health of the Chairman, who briefly replied, and then proposed the toast of the Secretaries, Dr. James Cagney and Surgeon-Major Carte, to which the former replied. During the evening songs were sung by Messrs. Daniel Price, Martin, and Edward Branscombe. An unexpected pleasure was afforded by Dr. Frederick Roberts, who, in response to a unanimous request, sang "The Anchor's Weighed."

HOSPITAL ABUSE AT BRIGHTON.

WE have received for publication the following letter, which has been sent by its medical signatories to the chairmen and committees of the various charities in Brighton and Hove, and which, as will be seen, supports the contention of certain of our recent correspondents:—

Nov. 4th, 1895.

GENTLEMEN,—We, the undersigned medical men, beg to call your attention to the gross and increasing "hospital abuse" in Brighton and Hove by a class of people well able to pay for private medical attendance. To no section of the community is this better known than to the general practitioner, who is constantly coming across people in well-to-do circumstances who do not hesitate to admit that they have had tickets for either in-door or out-door treatment at the various charities in the town. That 38,113 patients were attended at these charities during 1894 are figures which speak for themselves. This is quite independent of the workhouse and sanatorium, which would greatly add to the number. Of the 3704 births during 1894, a little over one-third were attended by the West-street Lying-in Institution. In addition to this, there were some attended in the unions, and others by the society for helping young women in their first fall. To many this would appear incredible, and we are sure that all will agree that it demands immediate explanation from that institution. We are given to understand that many of the patients are insured in the various benefit societies, where they receive a sum of money at the birth of each child, to help defray expenses. We are fully convinced of the fact that the institutions most abused are the general dispensary and those hospitals which are devoted to the treatment of special diseases. As medical men we are fully alive to the needs of the poor, who, in the hour of sickness or injury, require skilful and merciful attention; but we are also convinced of the fact that nothing is more demoralising than charity misapplied.

In conclusion, we appeal to the committees of the different charities in Brighton and Hove to use their best endeavours to put a stop to the abuse, which is not alone an injustice to the medical profession, which does so much gratuitous work for the poor, but at the same time is an injustice to the subscribing public, who have a right to demand that their generosity is not abused.

To the Chairmen and Committees of the various Charities in Brighton and Hove.

The importance of the general principle involved, as affecting not only Brighton but also every other large centre of population in the kingdom, can scarcely be overrated, and has for a long time past been pressed on the attention of our readers. A careful study of the question has convinced many that the ultimate remedy, or at least the most promising means of reducing the evil, is to be found in concerted and dignified action on the part of the honorary medical staff of the institutions whose beneficent charity has been curiously perverted into a means of introducing the lower middle class into the seductive paths of gratuitous relief. Becoming habituated to the out-patient room, and being inwardly convinced that their ailments entitle them to advice and medicine free of cost other than the hours of waiting spent in the society of like-minded sufferers, their honourable feelings of self-reliance and independence are discouraged, and under the pressure of loss of employment or increased illness the descent is easy to the relieving officer and the parish dole. It is unlikely that hospital committees and governing bodies will of their own initiative take any effectual steps to reduce the throng of applicants which besets their doors. From a managerial point of view it is very gratifying to produce at the annual meeting a report and statistics indicative of the popularity of the institution and holding out a prospect of an enlargement of the field of charity in the near future. Over and over again have we been told that the circumstances of applicants are investigated and that only a minute percentage of actual patients are in a position to pay something for medical attendance. The fact remains that, notwithstanding the great development of the medical departments administered by the Poor-law authorities, and the multiplication of medical charities and relief agencies of all sorts, the old-established hospitals show no substantial reduction in the numbers of those who are admitted to their benefits, and there is overwhelming evidence that such recipients of gratuitous medical aid bear no inconsiderable proportion to the general population. The question, in fact, is of urgent social importance, and our professional brethren will not misunderstand us if we express the opinion that the regrettable diminution of their patients in consequence of this "charitable" competition is an evil of less magnitude than the gradual habituation of the masses to the idea that thrift and self-reliance are matters of secondary importance.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6228 births and 4492 deaths were registered during the week ending Nov. 9th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 19·1 to 21·9 per 1000, further rose to 22·1 last week. In London the rate was 21·2 per 1000, while it averaged 22·7 in the thirty-two provincial towns. The lowest rates in these towns were 13·2 in Croydon, 14·7 in Huddersfield, 15·0 in Birkenhead, 15·9 in Leicester, and 16·6 in Nottingham; the highest rates were 26·3 in Plymouth, 29·5 in Salford, 33·4 in Wolverhampton, and 37·6 in Blackburn and in Liverpool. The 4492 deaths included 606 which were referred to the principal zymotic diseases, against 583 and 590 in the two preceding weeks; of these, 187 resulted from measles, 105 from diarrhœa, 100 from diphtheria, 90 from "fever" (principally enteric), 68 from whooping-cough, 54 from scarlet fever, and 2 from small-pox. No fatal case of any of these diseases occurred in Huddersfield; in the other towns they caused the lowest death-rates in Brighton, Croydon, Plymouth, and Nottingham, and the highest rates in Bradford, Liverpool, Salford, Wolverhampton, and Blackburn. The greatest mortality from measles occurred in London, Wolverhampton, Liverpool, Salford, Oldham, and Blackburn; from whooping-cough in Liverpool, Bradford, and Cardiff; and from "fever" in Bradford, Salford, Sheffield, and Wolverhampton. The mortality from scarlet fever showed no marked excess in any of the large towns. The 100 deaths from diphtheria included 75 in London and 4 in Wolverhampton. One fatal case of small-pox was registered in London and 1 in West Ham, but not one in any other of the thirty-three large towns. There were 78 small-pox patients under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 9th inst., against 119, 114, and 106 at the end of the three preceding weeks; 14 new cases were admitted during the week, against 7, 14, and 29 in the

Digitized by Google

three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2847, against 2838, 2833, and 2841 on the three preceding Saturdays; 349 new cases were admitted during the week, against 241, 269, and 215 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 235 and 366 in the two preceding weeks, further rose to 447 last week, and were 55 above the corrected average. The causes of 66, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Oldham, Leeds, Sunderland, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Preston, Sheffield, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·9 and 20·5 per 1000 in the two preceding weeks, further rose to 21·4 during the week ending Nov. 9th, but was 0·7 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·9 in Greenock and 16·3 in Edinburgh to 25·6 in Dundee and 29·2 in Perth. The 617 deaths in these towns included 23 which were referred to diarrhœa, 21 to whooping-cough, 10 to scarlet fever, 9 to "fever," 8 to diphtheria, 6 to measles, and not one to small-pox. In all, 77 deaths resulted from these principal zymotic diseases, against 65 and 69 in the two preceding weeks. These 77 deaths were equal to an annual rate of 2·7 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The 23 fatal cases of diarrhœa were within 2 of the number in the preceding week, and included 10 in Glasgow, 4 in Edinburgh, and 4 in Dundee. The deaths referred to whooping-cough, which had been 11 and 19 in the two preceding weeks, further rose to 21 last week, of which 12 occurred in Glasgow, 3 in Dundee, and 3 in Aberdeen. The 10 fatal cases of scarlet fever were within one of the number in the preceding week, and included 8 in Glasgow. The deaths referred to different forms of fever, which had been 12 and 6 in the two preceding weeks, rose again to 9 last week, of which 3 occurred in Glasgow, 3 in Leith, and 2 in Edinburgh. The 5 fatal cases of diphtheria, which had been 6, 9, and 5 in the three preceding weeks, rose again to 8 last week, and included 3 in Glasgow, 2 in Edinburgh, and 2 in Leith. Of the 6 deaths from measles 4 were recorded in Greenock. The deaths referred to diseases of the respiratory organs in these towns, which had been 130 and 136 in the two preceding weeks, further rose to 173 last week, and exceeded by 7 the number in the corresponding week of last year. The causes of 43, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·7 and 31·5 per 1000 in the two preceding weeks, declined again to 24·3 during the week ending Nov. 9th. During the past six weeks of the current quarter the death-rate in the city has averaged 24·8 per 1000, the rate during the same period being 18·5 in London and 17·7 in Edinburgh. The 163 deaths registered in Dublin during the week under notice showed a decline of 48 from the exceptionally high number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against numbers declining from 29 to 14 in the four preceding weeks; of these, 4 resulted from "fever," 2 from diarrhœa, 1 from diphtheria, 1 from whooping-cough, but not one either from small-pox, measles, or scarlet fever. These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 3·0 in London and 1·9 in Edinburgh. The deaths referred to different forms of "fever," which had been 5 and 2 in the two preceding weeks, rose again to 4 last week. The fatal cases of diarrhœa, which had declined from 17 to 4 in the four preceding weeks, further fell to 2 last week. The mortality from diphtheria and from whooping-cough corresponded with that recorded in the preceding week. The 163 deaths in Dublin last week included 27 of infants under one year of age, and 58 of persons aged upwards of sixty years; the deaths of infants showed a marked decline from the number recorded in the preceding week, while those of elderly persons considerably exceeded those recorded in any recent week. Four inquest cases and 2 deaths from violence were registered; and 54, or nearly a third, of the deaths occurred in public institutions. The causes of 18, or more than 11 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during October in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 14·5 per 1000 of the population, estimated at 4,392,346 persons in the middle of the current year. In the three preceding months the rates had been 11·6, 9·9, and 12·4 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. James Westminster, Hampstead, Bermondsey, Wandsworth, Lewisham, and Woolwich; while they showed the largest excess in Chelsea, Strand, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, and Greenwich. The prevalence of small-pox in London showed a marked decline during October, the 59 cases notified during the month including 14 in Camberwell, 9 in Bethnal Green, and 4 in Mile End Old Town sanitary areas. The Metropolitan Asylum Hospitals contained 103 small-pox patients at the end of October, against 232, 331, and 227 at the end of the three preceding months; the weekly admissions averaged 15, against 49, 57, and 27 in the three preceding months. The prevalence of scarlet fever in London showed a further marked increase during October; this disease was proportionally most prevalent in Chelsea, Strand, Holborn, Bethnal Green, Whitechapel, Mile End Old Town, St. Saviour Southwark, Rotherhithe, and Lambeth sanitary areas. The Metropolitan Asylum Hospitals contained 2727 scarlet fever patients at the end of October, against 2340, 2435, and 1845 at the end of the three preceding months; the weekly admissions averaged 243, against 263, 292, and 333 in the three preceding months. The prevalence of diphtheria in London also showed a considerable further increase during the month under notice; among the various sanitary areas this disease showed the highest proportional prevalence in Chelsea, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, St. Saviour Southwark, St. Olave Southwark, and Greenwich. There were 661 diphtheria cases under treatment in the Metropolitan Asylum Hospitals at the end of October, against 680, 666, and 664 at the end of the three preceding months; the weekly admissions averaged 103, against 103, 80, and 101 in the three preceding months. The prevalence of enteric fever in London showed a further increase upon that recorded in recent months; this disease was proportionally most prevalent in Hackney, St. Martin-in-the-Fields, City of London, Shoreditch, St. George-in-the-East, and Poplar sanitary areas. Erysipelas was proportionally most prevalent in St. Pancras, St. Giles, Holborn, Bethnal Green, and Mile End Old Town sanitary areas. The 24 cases of puerperal fever notified during October included 4 in Greenwich, 3 in Marylebone, 2 in Hackney, 2 in Bethnal Green, and 2 in Battersea sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, Nov. 2nd, the deaths of 7377 persons belonging to London were registered, equal to an annual rate of 17·5 per 1000 of the population, against 21·0, 16·9, and 16·0 in the three preceding months. The lowest death-rates during October in the various sanitary areas were 10·4 in Stoke Newington, 10·6 in Lewisham (excluding Penge), 12·2 in Hampstead and in Wandsworth, 12·3 in St. George Hanover-square, 13·1 in St. Martin-in-the-Fields, and 13·2 in Plumstead; the highest rates were 23·5 in Shoreditch, 24·3 in St. Saviour Southwark, 24·9 in Whitechapel, 26·6 in St. Luke, 27·7 in St. George-in-the-East, 30·8 in Limehouse, and 33·5 in St. Olave Southwark. During the five weeks of October 1133 deaths were referred to the principal zymotic diseases in London; of these, 327 resulted from diarrhœa, 307 from diphtheria, 214 from

measles, 112 from scarlet fever, 95 from enteric fever, 70 from whooping-cough, 6 from small-pox, and 2 from typhus. These 1133 deaths were equal to an annual rate of 2·7 per 1000; the lowest zymotic death-rates were recorded in Hampstead, Islington, Stoke Newington, St. Martin-in-the-Fields, Wandsworth, Lewisham, and Lee; and the highest rates in St. Pancras, Clerkenwell, Shoreditch, Bethnal Green, St. George-in-the-East, Limehouse, St. Olave Southwark, and Bermondsey sanitary areas. Six fatal cases of small-pox were registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being only 2; of these 6 fatal cases, 2 belonged to Bethnal Green, and 1 each to Chelsea, Limehouse, Battersea, and Wandsworth sanitary areas. The 214 deaths referred to measles were 57 above the corrected average; among the various sanitary areas this disease showed the highest proportional fatality in Westminster, St. Pancras, Clerkenwell, St. George Southwark, Newington, and Bermondsey. The 112 fatal cases of scarlet fever were 27 below the corrected average number; this disease showed the highest proportional fatality in Chelsea, St. Giles, Strand, Bethnal Green, Whitechapel, St. George-in-the-East, and Mile End Old Town sanitary areas. The 307 deaths referred to diphtheria were 109 above the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Hammersmith, St. Pancras, St. George-in-the-East, Limehouse, St. Olave Southwark, Rotherhithe, Greenwich, and Plumstead. The 70 fatal cases of whooping-cough were 49 below the corrected average; this disease showed the highest proportional fatality in Shoreditch, Poplar, St. Saviour Southwark, and St. Olave Southwark sanitary areas. The 95 deaths referred to enteric fever slightly exceeded the corrected average number; among the various sanitary areas the highest proportional fatality of "fever" was recorded in Hampstead, City of London, Limehouse, and Newington. The 327 fatal cases of diarrhœa were as many as 136 above the corrected average; this disease was proportionally most fatal in Paddington, St. Luke, Shoreditch, St. George-in-the-East, and Limehouse sanitary areas. In conclusion, it may be stated that the mortality in London during October from these principal zymotic diseases was more than 26 per cent. above the average.

Infant mortality in London during October, measured by the proportion of deaths under one year of age to registered births, was equal to 156 per 1000, and slightly exceeded the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, St. James Westminster, Stoke Newington, Strand, Lewisham, and Lee; and the highest rates in Paddington, St. Martin-in-the-Fields, Shoreditch, Bethnal Green, Limehouse, Newington, and St. Olave Southwark.

THE SERVICES.

The Ashanti Expedition.

The senior medical officers who are ordered to take part in the forthcoming Ashanti Expedition are Surgeon-Colonel W. Taylor, as Principal Medical Officer, and Brigade-Surgeon-Lieutenant-Colonel E. Townsend. The other medical officers have not yet been definitely selected. We understand that the troops will be provided with ten large portable Pasteur filters.

Movements of the Medical Staff.

Surgeon-Colonel Catherwood has arrived at Gibraltar in succession to Surgeon-Major-General Lewer, retired. Surgeon-Colonel Wilson has arrived from India, and has taken up the duties of Principal Medical Officer, York. Brigade-Surgeon-Lieutenant-Colonel O'Farrell has been appointed to the Home District on return from Egypt. Surgeon-Lieutenant-Colonel Allen has arrived from India to take command of the Depôt Medical Staff Corps, Aldershot. Surgeon-Lieutenant-Colonel Langridge, Surgeon-Major Dugdale, and Surgeon-Captain Cockerill have arrived from India on completion of a tour of service. Surgeon-Lieutenant-Colonel Powell and Surgeon-Major Donovan have embarked for India. The following officers have embarked for service in Bermuda:—Surgeon-Majors MacNeece and Baker, and Surgeon-Captain Corkery. Surgeon-Captain Ritchie has arrived from Malta on completion of a tour of service. Brigade-Surgeon-Lieutenant-Colonel Mackinnon (retired) has been appointed to Reading; Surgeon-Lieutenant-Colonel James to Canterbury; and Surgeon-Captain Elliott to the Women and Children's Hospital, Chatham.

Army Medical Staff.

Surgeon-Colonel John B. Hamilton, A.M.S., obtains promotion to the rank of Surgeon-Major-General, consequent on the recent retirement of Surgeon-Major-General Lewer.

India and the Indian Medical Services.

The services of the undermentioned officers (Bengal) are replaced at the disposal of the Government of the North-West Provinces and Oudh:—Surgeon-Major F. D. C. Hawkins, Surgeon-Captain W. G. P. Alpin, Surgeon-Captain W. Vost, Surgeon-Captain J. Chaytor-White, and Surgeon-Captain H. B. Melville. The services of the undermentioned officers (Bengal) are replaced at the disposal of the Government of the Punjab:—Surgeon-Captain C. H. James and Surgeon-Captain D. T. Lane. The services of the undermentioned officers (Bengal) are replaced at the disposal of the Government of Bengal:—Surgeon-Major F. S. Peck, Surgeon-Captain E. H. Brown, Surgeon-Captain F. O'Kinealy Surgeon-Captain B. C. Oldham, and Surgeon-Captain B. H. Deare.

Naval Medical Service.

Fleet-Surgeons: R. M. Loftie to the *Medea;* R. G. Brown to the *Medusa.* Staff-Surgeons: E. R. Dimsey to the *Phœbe,* when recommissioned; J. L. Bagnall Oakley to the *Sappho;* Ernest E. Bray to the *Thunderer.* Surgeons: H. St. D. Griffiths to the *Swallow;* R. Hickson to the *Vivid;* Johnston H Acheson to the Cape of Good Hope Hospital; Francis H. A. Clayton to the *St. George;* and Percy H. Bayden to the *Thrush.* Surgeon and Agent: J. E. Webb, M.B., retired Surgeon, R.N., at Looe and Polperro.

Volunteer Corps.

Rifle: 1st Volunteer Battalion the Lancashire Fusiliers: Arthur Peel Nuttall, M.B., to be Surgeon-Lieutenant. 1st Surrey (South London): Louis John Gerard Carré, M.D., to be Surgeon-Lieutenant.

Volunteer Infantry Brigades.

Essex Brigade: Surgeon-Major E. Shedd, 2nd Volunteer Battalion the Essex Regiment, to be Brigade-Surgeon-Lieutenant-Colonel.

The Japanese Army Medical Service.

That the Japanese are a most intelligent and enterprising people has been long known, but recent events have shown that they are a really remarkable nation as regards their courage, energy, thoroughness, and power of organisation. Surgeon-Colonel W. Taylor gave a very interesting account of the medical military arrangements of the Japanese army in the field at Aldershot on Tuesday last. In the absence of the Duke of Connaught, the chair was taken by Major-General Sir William Butler. It will be remembered that Surgeon-Colonel Taylor was sent out by the British Government during the Chino-Japanese War to observe and report upon the field medical arrangements, and that what he had to say at Aldershot was therefore based upon the results of his personal experiences and observations. He described the medical regulations of the Japanese service as being very full and complete, and declared that they were carried out to the letter and most successfully. So excellent was their system and so modern in its conception that he did not believe that a single life was lost that could have been saved, and he went on to add that Japan had little or nothing to learn from Germany or England in respect of her hospital service arrangements. This is enthusiastic and, as we believe, well-merited praise. In the discussion that subsequently ensued Surgeon-Major-General Paterson remarked that from all he had heard he inferred that the organisation of our own military medical service was not so advanced as that of Japan. General Butler, the chairman, declared that the descriptions given in the lecture were a revelation to them. It was a triumph of organisation, and no doubt a good deal of it was to be explained by the fact that the Japanese had adopted the German system.

The French Expedition in Madagascar.

The large amount of sickness that prevailed among the French troops in Madagascar, followed, as it was, by heavy losses in mortality and invaliding, continues to attract the attention of the French press. The expedition was, no

Digitized by Google

doubt, for various reasons one of unusual difficulty, and the amount of sickness from malaria and other causes was probably in a large measure unavoidable and far greater than had been expected; but it must be confessed that there seems to have been a lamentable want of foresight as well as mismanagement in arranging and providing for the requirements of the campaign, especially in regard to the supplies, transport, hospital, and hygienic arrangements for the troops, who seem to have been too largely composed of young and unseasoned soldiers. The Ribot Ministry has fallen and been succeeded by another Government, and we shall probably never learn now the whole extent of the French losses. General Duchesne and his troops have achieved a great military success in Madagascar, but at a cost of life which we sincerely regret.

On Nov. 6th the *Britannia* brought ninety-seven cases from India to Netley for admission to the wards of the Royal Victoria Hospital.

Correspondence.

"Audi alteram partem."

"THE BRITISH MEDICAL BENEVOLENT FUND."

To the Editors of THE LANCET.

SIRS,—I shall be glad to avail myself of your kindness to acknowledge in your columns the sums already received in answer to my appeal of last week, and to thank most heartily those who have so promptly come to our relief. In several cases members of the British Medical Association have sent us the half of their subscriptions returned after paying the expenses of the meeting in London last summer, and we should have reason to be very grateful if this example were followed by others. The present embarrassed state of the fund is caused, not by a falling off in the subscriptions, but by the non-arrival of large donations, which are always an uncertain source of income. Besides these may be mentioned a donation of £21 from Mr. France, a member of the committee, £5 from Mrs. Cæsar Hawkins (in addition to a previous donation of £10 10*s.*), and £10 10*s.* from the Treasurer.

Subscriptions and donations may be sent to the Treasurer or to the Hon. Financial Secretary, Dr. Samuel West, 15, Wimpole-street.

I am, Sirs, yours faithfully,
W. H. BROADBENT.

84, Brook-street, Grosvenor-square, W., Nov. 13th, 1895.

UNITED KINGDOM POLICE SURGEONS' ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—In consequence of the circular issued by the late Home Secretary, Mr. Asquith, to those borough and city councils which had not hitherto appointed police surgeons, many new appointments have been made. Notices of some of these have been sent to us, and in each case a nomination paper has been sent. But there may have been some gentleman appointed of whom we have not heard and who may wish to join this association, of which Sir H. D. Littlejohn is the President, which has already done so much to promote the interests of police surgeons.[1] Will you kindly allow us to state that we shall be most happy to send a printed form of application for membership to any newly appointed police surgeon who is not already a member?

We are, Sirs, yours faithfully,
FRED. W. LOWNDES,
40, Knight-street, Liverpool;
H. CULLIFORD HOPKINS,
6, Bladud-buildings, Bath;
Nov. 11th, 1895. Hon. Secretaries to the Association.

[1] THE LANCET, Nov. 9th, 1895, p. 1177.

VARICOCELES AND THE SERVICES.

To the Editors of THE LANCET.

SIRS,—In what way does a varicocele—excluding those very rare cases of excessively large varicoceles—incapacitate a man? I suppose nineteen men out of every twenty have a small varicocele, yet they do their work and live to a good old age and never know they are suffering—no, not suffering—are the subjects of this all-important—in the eyes of the Government, at any rate—complaint. Why then, I ask, are young men wishing to enter one of the Services compelled first to undergo an operation if they happen to be the possessors of varicoceles? But what I most object to is that hospitals—we are constantly getting them at the one I am connected with—have to admit these fine, healthy young lads and board them for three weeks. If the Government will insist on observing this regulation it ought certainly to pay for the board of these cases. It is hardly fair to use subscribers' money to feed perfectly healthy young patients, but as the regulations at present stand we cannot refuse to admit these cases and so fit them to earn their livelihood in one of the services.

I am, Sirs, yours faithfully,
C. F. WIGHTMAN, F.R.C.S.Eng.

Chichester, Nov. 12th, 1895.

*** Varicocele is without doubt a condition very frequently met with, but we are inclined to think that it is by no means so frequent as our correspondent suggests. It is probable that its presence, in the slighter forms at least, is not the cause of any pain or uneasiness even after severe exertion, but it has been found that men in the army or navy are very prone to complain of pain in a varicocele when they are required to undertake any unusually great exertion, such as a long march; therefore, it has been deemed advisable to decline to enlist any men suffering from this condition, not because the variocele in any way really interferes with the due performance of a soldier's or a sailor's duties, but because it proves a fruitful source of malingering. The cost of curing a man with variocele should fall, if possible, on the man himself, but if, as is usually the case, he be unable to defray this expense, then it is not unreasonable that hospitals as charitable institutions should assist him. The Government can hardly be expected to afford pecuniary help to enable a man who wishes to enlist to comply with the conditions of enlistment.—ED. L.

THE ADMISSION OF WOMEN TO THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—There is a time-worn story to the effect that, when Stephenson was engaged in pushing his first Railway Bill through the House of Commons, he met with strenuous opposition from some of the older members. One of these, thinking to give him a poser, suggested that a cow might get on the line in front of a passing engine. "Well," said Geordie, with a twinkle in his eye, "so much the worse for the coo." Now, Sirs, it is with no little concern that one sees the Colleges to which one belongs taking up the position of Stephenson's "coo." No one who can read the signs of the times can doubt that women have made up their minds to study medicine. It is equally obvious, from the way in which they succeed in practice, that they have the support of the public. This being the case, it is plain that if the Colleges persist in standing in the way of this movement they will do no damage to the women, but will certainly damage themselves. Surely, after so many thousands of years' experience of the respective merits and

Digitized by Google

demerits of the two sexes, the public may be allowed to judge for itself whether women are fitted to become its medical advisers or not. This is for the public to decide, and not the Colleges. Their province ought to begin and end with their professional qualifications and that which pertains to them. But when the public has expressed a demand for medical women it is an abuse of the privileges of the Colleges, and a shirking of duty, to refuse to put their hall-mark on those who come up to their standard. For my own part, I believe that women are not so well qualified by nature for the work of our profession as are men. But I cannot conceive how anyone can now bring this forward as an argument for refusing them a diploma. The only ground which would render such an action justifiable would be that the diploma is not worth receiving. I am not of that way of thinking myself. I believe it is not often that anyone passes the examinations who is not medically fit to be trusted with the lives of his fellows. But it is for just this reason that women, even more than men, ought not to be denied these tests. Neither does it seem quite reasonable to refuse to remove an obstacle to their progress on the score that they are already handicapped by nature. One effect of this short-sighted policy of the Colleges will be to give a quite artificial spurt to the medical education of women. I suppose it will be impossible for all women to henceforth work up for the degrees of the London University. If they do, it will be a fine revenge on the Colleges to altogether ignore them in the future. But what will undoubtedly happen will be that more women will be driven to seek their education elsewhere than in London, and more will enter for the London degrees. This latter alternative means that the women will acquire a value in the eyes of the public altogether disproportionate to that of the same number of men; for the public estimates its medical men mainly according to their professional qualifications and attainments, all other considerations being secondary. In fact, this action of the Colleges will act as persecution always does. It will strengthen the influence of the persecuted, and weaken that of the persecutors.

To a reader of the report of the discussion in THE LANCET of Nov. 9th it looks very like a covert sneer at the President for one to say that women do not make good surgeons, while another dreads lest they become Fellows and Presidents! Is it possible that the Fellows and Presidents are always chosen from among the most incapable of the profession? I am sure I am not alone when I say that I shall heartily welcome the election of a woman President if she deserve it. Such questions as this ought to be decided on no other ground than that of merit, and not according to the cut of the clothes, the shape of the face, or other peculiarities of sex. In fact, the report reads like a chapter from the writings of Swift; and there is a deal of unconscious irony in the fear that was expressed lest the College should fall under petticoat government. The debate of the physicians was apparently more dignified in tone; but it is sad to see the names of so many honoured leaders of the profession on the side of such ultra-conservatism.

In conclusion, Sirs, I should like to explain that I do not desire to set up as the champion of the women, who have shown that they can very well take care of themselves, but I wish to protest against the action of the majority at these two meetings, seeing that it is calculated to bring the Colleges into contempt. I am, Sirs, yours truly,

Reading, Nov. 9th, 1895. HASTINGS GILFORD.

To the Editors of THE LANCET.

SIRS,—I should like to say a few words on this subject of admitting women to the examinations of these corporations. One of the lay papers speaks of the refusal of the Royal College of Physicians of London to admit women to their examinations as being "the extreme of pettiness,"[1] since the Royal Colleges of Edinburgh and Dublin have opened their portals to women. As members of the medical profession we cannot too clearly express our thanks to the Censors of the London College for having refused their growing demands to be admitted where they are neither required nor wanted, and we do sincerely hope that the Royal College of Surgeons will follow such an example by a very much larger majority. Surely, because other corporations have committed a great error this is no argument why we should seek to copy such evil examples. We do not seek to decry the abilities of some women. But from a physical, physiological, and moral point of view we would urge women not to seek to still further unsex themselves. When women first claimed to enter the medical profession they put forward as one of their strong arguments the sad condition of the women of India, who were not allowed to be attended by male practitioners. We now have the very weighty statement of no less a distinguished member of our profession than Sir Joseph Fayrer, who stated at the meeting of the Royal College of Physicians of London that "so far as his experience went there was no difficulty in the way of medical men entering the *most jealously* guarded harem when there was need for their services." There is one very important point which seems to have been lost sight of, and that is, if women are admitted to the Fellowship of the Royal Colleges of Physicians and Surgeons of London, what is to prevent their occupying the various professorial chairs? We should then have the glaring anomaly of women teaching the men. This is no fancy picture, for with their ever-increasing demands it would only be a matter of time. Dr. West justly says: "What had they done for midwifery, which for a century and a half was entirely in their hands?" I would go a great deal further, and say that the modern medical women are doing more to degrade and lower the standard of the profession than any body of medical men have ever done, for they are at the present time seeking to attend midwifery for a fee of 5*s*., and for aught I know for even less than that. Does this show that there is any great and growing demand for the services of medical women even for members of their own sex? And from a recent glaring case we have distinct evidence that women from their teaching and practices are prepared to inculcate acts of direct and open immorality. From a physical point of view I know of nothing that is more arduous or trying for the powers of a *strong* man than is a large midwifery practice; and yet it is just this particular branch of the profession which the women claim as peculiarly their own. There is a great deal more which I could say against their claims, but I will not trespass further upon your space. I would, however, urge upon the Council of the Royal College of Surgeons to reject this application by every means in their power. I feel perfectly certain in my own mind that if the 16,000 members of the Royal College of Surgeons had their just demands conceded to them of voting on matters of vast importance which affect the Members so deeply, the vote on the present occasion would be such an overpowering majority that the application of these women would be emphatically refused; and if the other Royal Colleges had been in a similar position women would never have gained a footing into our profession at all.

I am, Sirs, yours faithfully,

London, Nov. 4th, 1895. ALBERT S. MORTON.

[1] The Queen.

HOSPITAL ABUSE.

To the Editors of THE LANCET.

SIRS,—Two cases have come under my notice which show what large sums the poor are able to pay in order to obtain free treatment at a hospital. One, an agricultural labourer living near Stockbridge, attended Moorfields Hospital for myopia from May, 1890, to June, 1893, and paid altogether twelve visits to the hospital. The other, a woman from this neighbourhood, also suffering from myopia, attended Moorfields Hospital from July, 1890, to November, 1893, during which time she paid sixteen visits to the hospital. The man must have spent about £6 and the woman about £8 in travelling expenses alone, not counting the loss of time, and as they were each using atropine drops and taking Donovan's solution during the whole time of their attendance they must have cost the hospital an appreciable sum. It thus appears that the charitable treatment of these two cases (and they are probably typical of a large class) involved a greater expense than is usually incurred by well-to-do persons who pay fees for advice. I am, Sirs, yours faithfully,

Southampton, Nov. 11th, 1895. J. F. BULLAR.

"CHRONIC NASAL OBSTRUCTION."

To the Editors of THE LANCET.

SIRS,—The connexion, pointed out in your last issue by Mr. Mayo Collier, between nasal obstruction and a high-arched palate is one of the most remarkable facts in

Digitized by Google

pathology. Since Mr. Collier first drew my attention to it, now some two or three years ago, I have had repeated opportunities of verifying it, and I can have no doubt that the vast majority of high-arched palates are due to nasal obstruction. But in what way? The explanation given by Mr. Collier, though not mentioned in his letter, appears to be the right one. It is that nasal obstruction leads to a diminution of the atmospheric pressure within the nasal passages—a fact that can be experimentally demonstrated—and that the pressure on the under surface of the bony palate being thus during several years of developmental life, when it is plastic and yielding, greater than that on the upper surface, it is driven upwards, producing a narrow, high arch and all the numerous secondary effects referred to by Mr. Collier. These considerations accentuate the importance of operating on all cases of "adenoids" without delay.

I am, Sirs, yours faithfully,

Devonshire-street, W., Nov. 11th, 1895. HARRY CAMPBELL.

THE USE OF DRUGS.

To the Editors of THE LANCET.

SIRS,—As a result of Dr. Gowers' address on the Use of Drugs, delivered before the Willesden and District Medical Society at the inaugural meeting of the present session on Oct. 11th, the executive of the society have decided that there shall be a discussion at a subsequent meeting on a few of the drugs considered to be most useful in general practice. Each member was asked to send in a list, and from these lists the following drugs have been selected: iodide of potassium, antipyrin, liquor arsenicalis, tinctura digitalis, and liquor strychniæ. Dr. Samuel West has kindly promised to open the discussion, which will, it is hoped, take place on Friday, Dec. 20th. I am, Sirs, yours truly,

Harlesden, Nov. 12th, 1895. ALFRED BINDLEY, Hon. Sec.

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1157.)

MEDICAL ETHICS AND THE DISPENSARIES AT HULL.

THOUGH the medical profession is not as united and as unanimous as might be desired at Hull, still the actual state of affairs here is far more favourable to the cause of union than in the neighbouring and rival town of Grimsby. At least, there is at Hull a local medical society, and nearly all the practitioners of the town are members of that society. It was founded in 1889, and it was originally called the Medical Ethical Society of Hull. At that time about fifty medical men belonged to the local branch of the British Medical Association, and it was thought that this organisation was not strong enough to deal with matters of ethics. To exercise wholesome influence on such questions a purely local society, it was imagined, would be able to gather together a larger number of practitioners. Therefore, the Medical Ethical Society of Hull was formed, and its objects were (1) the discussion of scientific subjects, and (2) the promotion of a closer union between the members of the profession by the holding of at least two general meetings annually to decide between medical men any ethical questions that might be pending. Some ethical rules were framed and accepted, and these forbade the employment of agents to solicit practice, advertising, the distribution of handbills, &c. Unfortunately, there was a good deal of backsliding. Though the enormous majority—more than 90 per cent.—of the local practitioners are absolutely unanimous on these points, it sufficed that two or three medical men should prove false to the cause to upset the whole combination. For instance, it was agreed that no practitioner should accept any club practice at less than 4*s.* per member per annum. This rule was loyally adhered to by all except one, who secretly agreed to take club members at a smaller figure. By this means he secured such a large number of clubs that suspicions were awakened, whereupon the other members of the profession engaged in club practice, in hot haste and in self-defence, abandoned the 4*s.* minimum. This prevented all the clubs going to the one man. The spirit of competition, however, was let loose again. Practitioners soon began to underbid each other, till the payments for contract work dropped from 4*s.* to 2*s.* 6*d.* At first the Medical Ethical Society of Hull did a great deal of good; but later it was discovered that two of its members were distributing handbills. The society invited them to appear before the society's council, but the medical men in question simply sent in their resignations. The society thus lost all jurisdiction over them. It is true that complaints were made to the licensing bodies from which the practitioners in question had received their qualifications, and the latter were duly warned, and it is believed that they have not issued any further handbills. In the meanwhile, however, they had fully profited by whatever advantage such publicity can bring. I made a point of calling on one of the medical men in question, feeling that it would be very useful to know what were his arguments and views on the point at issue. I was courteously received, and the conversation that ensued was of a most interesting character.

The practitioner in question was, I found, very bitter against friendly societies and against charitable dispensaries. He urged that the dispensary at Hull organised by the friendly societies was opposed to trades-unionism. He marvelled at the inconsistency of the members of these friendly societies, who for the most part were themselves trades-unionists and yet acted against the spirit of trades-unionism. He thought that a trades-union strove to keep each man to his trade and should not allow a trades-unionist to employ his leisure moments in "blacklegging" some other trade. What would be said, he urged, if the practitioners of the town were to combine to open a butcher's or a grocer's shop? This observation was, however, somewhat wide of the mark. Many trades-unionists are very active coöperators. At the trades-unionist congresses delegates from coöperative congresses have often been heard and received as honoured guests. Trades-unionists are not opposed to such coöperative efforts as tend to eliminate the middleman or tradesman and bring the consumer in more direct relation with the producer. I take it the case may best be put in this manner: In the study of chemistry and of dispensing, in the practice of dissecting, in the performance of operations and the dressing of wounds, medical men have to acquire a facility of delicate manipulation which befits them for many skilled handicrafts. Therefore many medical men could with ease employ their leisure moments in some sort of productive industry, as the making of scientific instruments, works of art, photography, &c., and could thus compete, undersell, or "blackleg" in some of the productive industries with which trades-unionists are concerned. As matters now stand, and viewing the economical side of the problem, the medical man has this advantage over the artisan engaged in a productive industry, that he is in direct communication with the "consumer," and that, as a rule, no factory owner and tradesman step in between his work and the patient he attends to take a portion of the money paid for such work. The point now at issue is whether this favourable state of affairs is compromised by the action of the dispensaries which the friendly societies have established. They certainly compete with the druggists' trade. Do they pay trades-union wages to their dispensers or do they profit by the want of organisation among dispensers to pay the lowest competition rate of wages? Do they not also pay a low competition rate of salary to their medical officers, sweat a profit out of their labour, and employ them in a manner that by competition must tend to reduce the rate of remuneration given to all medical men who do contract or club work? If so—and but little doubt can be entertained on this point—then the dispensaries established by the friendly societies are not in harmony with the principles generally advocated by the trades-unionists of this and of all other countries. As so many members of these dispensaries are trades-unionists this is certainly a point that must be kept well in view and that will be of great use in the effort which should be made to reform these institutions.

The medical man on whom I called claimed that if anyone had a right to organise medical aid it was the medical men themselves. He had, therefore, resolved to establish a medical club of his own, but he found that medical etiquette clipped his wings and handicapped him heavily in his efforts to compete against medical clubs organised by laymen. Close at hand a number of workmen and tradesmen, persons who had nothing whatsoever to do with the medical profession, had opened what was practically a druggist's shop

Digitized by Google

and a medical consulting-room. They could issue handbills, they could employ agents and solicit practice and do anything they chose, however unprofessional it might be, because they were laymen. The medical men they employed were merely their servants and had no power to prevent such practices. Thus the dispensaries organised by the friendly societies had great advantages when competing against the dispensaries organised by medical men. Undoubtedly it was *infra dig.* for medical men to advertise or to issue handbills, but then dispensaries managed by laymen should also be debarred from employing these tradesmanlike methods. But dispensaries founded by laymen were not only unmindful of professional dignity and etiquette, they were equally unmindful of professional interest. What was the question of wage limit to them? It did not affect them in the least. It was not a loss to a friendly society that a large number of their members should be in receipt of good incomes; if anything, this was an advantage rather than a disadvantage. The clubs would not impose a wage limit; the profession alone would do this. At present he knew one man, living in a villa worth £50 a year in rent, who was suffering from hemiplegia and who had been constantly under medical care though he only paid 3*s.* a year. He had retired from business, was enjoying ample means, and yet still resorted to the services of the club officer. Then, again, to obtain a medical practice it was necessary to compete, not only against friendly societies, insurance companies, and other commercial speculations that organised medical aid, but also against hospitals and public charities that were likewise grossly abused and gave gratuitous medical aid to people who could well afford to pay. The employers of labour in Hull often shirked their responsibilities by subscribing to the infirmary or the Hull Dispensary, both endowed charitable institutions. If an accident happened, the employer gave a ticket to his injured workman. The profession thus lost a paying patient, and the sufferer's condition was often aggravated by the time required to remove him to the infirmary. In minor cases the cost of the cab fare to the infirmary would have paid the medical attendant's fee. The manner in which subscribers indiscriminately gave tickets for charitable institutions was a grave abuse; and these institutions, which took away so many of the patients who should go to the profession, were allowed to advertise to any extent and to canvass for charitable donations. Thus, in one way or another, canvassing and advertising were constantly employed to the disadvantage of the private and independent practitioner, with the result that it took away many of his most likely patients; but the private practitioner was not allowed to use the same weapons in self-defence. He was quite willing to condemn such means, but thought they should be condemned all round. With regard to the distribution of tickets for hospitals and endowed charitable dispensaries, he thought these should be left in the hands of the profession. None knew better than medical men themselves what patients they were willing and able to attend and whether such patients could afford to pay. The town of Hull was overrun with charities that pauperised the people, undermined their sense of independence, and created such a competition against private practitioners that they lowered the tone of the entire profession. As a remedy for the deplorable situation thus created, he suggested that the distribution of tickets for charitable institutions should be transferred from the givers of donations to the members of the profession. With regard to friendly societies and club practice generally, he thought that, in spite of the keen competition between the medical men at Hull, it would be feasible to follow the example given at Eastbourne and amalgamate all the club practice in one great organisation managed by the members of the medical profession themselves. Then, and then only, would it be possible to enforce something like a wage limit.

Such, as far as I was able to gather, were the main arguments of one of the medical men who withdrew from the Medical Ethical Society of Hull. It will be seen that they were not devoid of force; and I could not help thinking that such secessions are due, not to any disapproval or opposition to the ethical base it is sought to establish, but rather to a lack of faith in the ability of the medical societies to carry out their principles. In other words, if the medical unions were stronger, their discipline more firmly enforced, and their activity greater, there would be less tendency among the members to secede. It must, however, be confessed that the Hull Medical Society, as it is now called, perhaps because it was not very successful in enforcing its ethical principles, is somewhat weak-kneed. Another practitioner, who also resigned from this body, has established dispensaries in Hull on such a thoroughly commercial basis that it was the general opinion that the profession should break off all relations with him and refuse to meet him in consultation. Acting according to this opinion, one well-known practitioner did refuse to meet the medical man in question, but the latter had only to cross the street and he at once found another consulting physician who readily accepted the call. The attempted action thus broke down. Yet nothing would better shake the confidence of people who subscribe to the dispensaries of advertising medical men if it was known that eminent men in the profession would not meet such practitioners in consultation. This is the one effective weapon the profession possesses. The difficulty, however, is to persuade the consulting physicians to take an active part in the movement. The struggling practitioner, the young medical man who is vainly looking about for a good opening, feels, and feels keenly, all these grievances, but the senior members of the profession would sometimes seem to take only a passive interest in the question—it rarely touches their pockets. Several practitioners to whom I spoke urged that the heads of the profession were the greatest sinners. "We must have a good example from above," they exclaimed. "What are we to do when a consulting physician visits a patient three times for a guinea, and men who have been fifty years in the profession will drive miles out into the country for a 5*s.* fee?" The principal grievance at Hull would have been nipped in the bud if the consulting physicians had acted in harmony with the general and freely expressed opinion of the profession and had refused to meet one or two medical men whose conduct was unanimously condemned. The Hull Medical Society now numbers eighty-five members, and, even including the house surgeons at the infirmary, &c., there are barely 100 practitioners in the town. So numerous an organisation should be master of the situation, but it is no use uniting if when united no action is taken. In two grave instances mentioned the offending members were allowed to have their own way. On the other hand, it must be said that these incidents occurred some years ago, when the necessity of making a stand was not keenly appreciated. After all, a great deal of preparation must precede the adoption of active measures. These can never be enforced till their wisdom and their usefulness are approved and understood. Now, however, the time has come when the need of firm and united action is impressing itself upon the minds of an ever-increasing number of medical men. There is good ground to hope for a better future.

Hull, Nov. 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday and Saturday in Liverpool: the Annual Meetings.

AT the annual meeting of the supporters of the Hospital Sunday collections, on the 4th inst., the committee reported with regret that the depression which began to affect the Fund in 1892 had not shown any sign of lifting, the Fund having declined gradually from £6973 in 1891 to £6155 in 1895. A hope was expressed that the recent improvement in trade and manufacture might reasonably be expected to react upon the Fund and that a better result might be looked for in 1896. All things considered the committee were well pleased that so large a sum as £6155 had been realised. It was not considered desirable to change the date, as had been proposed. At the Hospital Saturday meeting on the 6th inst. it was stated that the fund was increasing year by year, the total collected this year being over £5000. The Lord Mayor, who presided, remarked that it was creditable to the working men of Liverpool that they had taken up the movement so earnestly.

Rabies in Lancashire.

A number of persons were fined at Prescot Police-court on the 5th inst. for having their dogs insecurely muzzled. As justifying the rigorous enforcement of the muzzling order it was shown that between April 25th and Oct. 16th there had been in the county 25 certified rabid dogs, which had

Digitized by Google

bitten 13 persons. There had also been 3 deaths from hydrophobia, while 84 persons had been bitten by dogs not certified to be rabid.

A Black Assize.

The commission for the autumn assizes of South-west Lancashire, always held in Liverpool, will be opened on the 14th inst. The calendar is a very heavy one, there being already 82 prisoners for trial, which number will be increased during the interval between to-day and the discharge of the grand jury. The charges comprise 7 against prisoners charged with murder, 2 with attempted murder, 8 with manslaughter, 15 with wounding, and 15 with criminal assaults. Mr. Justice Henn Collins is expected to preside in the Crown Court.

The Liverpool Crematorium.

If one may judge from the large number of citizens, medical and lay, who express their approval of cremation as a mode of disposal of the dead, the success of the new city crematorium, which is rapidly approaching completion, ought to be assured. The manager's house, with waiting-room and office, are expected to be ready for occupation about the end of the year, and the acting sub-committee propose shortly to appoint a resident manager and to prepare for undertaking public cremation.

How Typhoid Fever is Spread.

At the St. Helens Police-court on the 11th inst. a farmer was summoned for failing to furnish the Corporation with the names and addresses of his customers, infectious disease having been attributed to milk supplied by him. The facts were that at the beginning of last week the medical officer of health received seven notifications of cases of typhoid fever, and found on inquiry that all had been supplied with milk from the defendant's farm. The usual notice was served upon him requiring him to give a list of his customers, but he failed to do so. His solicitor, however, furnished a list on his client's behalf, and on undertaking to pay the costs the charge was withdrawn. It was stated that the defendant himself was now laid up with typhoid fever, the fever having been most probably caused by the filthy state in which his premises were kept.

Lord Derby and the Infirmary for Children.

Following a time-honoured custom, the Right Hon. the Earl of Derby, the newly elected Lord Mayor of Liverpool, attended Divine service at St. Peter's Cathedral Church on Sunday, when a sermon was preached and a collection was made on behalf of the Bluecoat Hospital, the oldest city charity. Following a more recent but well-established custom, his lordship also visited the Infirmary for Children, being accompanied by Lady Derby, and visiting all the wards, attended by members of the committee and of the medical staff.

Nov. 12th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary, Newcastle-upon-Tyne.

AT a quarterly court of governors held in the above-named institution on Thursday, Nov. 7th, Miss Emily Aston was appointed matron; Mr. Page was reappointed surgeon for a further period of fifteen years; Mr. Morrison, assistant surgeon; Mr. Markham, dental surgeon; and Professor Bedson, analytical chemist—each for a further period of seven years. Dr. Drummond resigned the office of pathologist, which he has held for fifteen years, and was cordially thanked for his valuable services. The deputy mayor, who was in the chair, announced that the income for the year up to the present date showed an increase of £1283, and that there was a balance in favour of the institution in the banker's hands. This is quite an unusual financial position for the infirmary to occupy at this time of the year. A most significant and gratifying fact is the marked increase in the subscriptions from the workmen. Their contribution, so far, amounts to £2000, being an increase of nearly £500. The workmen are fully represented on the committee of management, and take a very active part in the administration of the infirmary. The committee has been enlarged; the workmen will in future send twelve representatives, and the city council two. The members of the consulting staff are also made members of the committee, and these additions raise the number to thirty-seven, a somewhat large body.

Mayor's Sunday.

Yesterday, being the first Sunday after Nov. 9th, the mayor, sheriff, aldermen, magistrates, and councillors, according to custom, went in state to St. Nicholas' Cathedral, Newcastle-upon-Tyne, where the Rev. Canon Gough, the vicar, preached a sermon in aid of the medical charities of the city—an eloquent and scholarly sermon to which it was an intellectual treat to listen. It is sincerely to be hoped Canon Gough may preach on many similar occasions, but the translation of the late vicar, Canon Lloyd, to the Bishopric of Thetford, warns us that we may not be able to keep amongst us our present able and eloquent vicar. Formerly the whole of the offertory on Mayor's Sunday used to be given to the Infirmary, but in the year 1870 the Hospital Sunday movement was adopted in Newcastle, and since then there has been a common fund for the medical charities. Nearly £90,000 have been raised by the Hospital Sunday Fund during the twenty-five years of its existence, and a special appeal having been made this year it is anticipated the yield will be larger than on any former occasion.

South Shields: a Good Example.

On the occasion of the election of the new mayor at South Shields the retiring mayor, Alderman R. Redhead, handed to his successor, Councillor John Bowman, a cheque for £105, saying, "Before the completion of his year of office as mayor he should like to do something towards an extension of the Ingham Infirmary at South Shields."

Children in Workhouses.

There are some 500 Roman Catholic children in workhouses in the north of England. With a commendable anxiety for the betterment of these children, a bazaar on an extensive scale was held last week in Olympia, the largest public building in Newcastle-upon-Tyne. The object is to raise money with which to build homes, where, under Roman Catholic influences, these children may be trained and educated. The feeling that this is a better way of bringing up children than in a workhouse is not confined to Roman Catholics, for upon the bazaar committee, in addition to the names of many influential Roman Catholics, are those of some well-known Protestants. When the Protestants follow so good an example and make an effort to remove their children from workhouses, no doubt the Roman Catholics will in like manner lend their aid—one good turn deserves another. The bazaar was closed on Saturday night by the right worshipful the Mayor, Mr. Riley Lord, and the sheriff, Mr. G. Harkers, this being their first public function since their election. It is announced that a sum of some £3000 has been raised by this most successful effort.

The Durham College of Science.

This college continues to thrive at Newcastle, and many gratifying pieces of intelligence are contained in the principal's report just issued. The number of students taking regular courses and giving their whole time to the college during the past year has increased and reaches the respectable figure of 219. The total number of students, day and night, male and female, last year was 1370, and there has been a considerable increase in the number of students presented at the University of Durham for the A.Sc. and B.Sc. degree. To finish this magnificent college, and there is certainly no finer in the United Kingdom, some £40,000 are required, and it is to be hoped that at no distant period this somewhat large sum of money will be forthcoming and the valuable educational institution, so ably presided over by the energetic principal, Professor Gurney, completed.

Ill-treatment of Children again: Exemplary Punishment.

At the instance of Inspector Appleton, the vigilant officer of the Society for the Prevention of Cruelty to Children, a labourer named Harken was last Friday brought before the Newcastle-upon-Tyne magistrates charged with cruelly ill-treating two of his children by kicking them. The inspector stated "the boys were in a most shocking state." The chairman said "the case was one of the most grievous he had ever had before him," and sentenced the prisoner to six months' hard labour. What will become of these unfortunate boys and the three other children while their father is being clothed and fed and housed at the public expense during the winter? It is to be feared they will have to live on their

Digitized by Google

mother's scanty earnings, which means that they will be ill-fed, ill-clothed, and ill-housed. Had the law allowed it, the court might have awarded Harken a sound flogging, a punishment he richly deserves, and one which would go far to deter other parents from kicking their children till their bodies are covered with bruises.

Death of Mr. W. C. Blackett.

At Ripon, last week, at the age of sixty-four, died a much-respected member of the medical profession, Mr. W. C. Blackett, M.R.C.S. Mr. Blackett practised in Durham and took a leading part in city matters. In 1888 he was elected mayor of Durham. The *Newcastle Daily Chronicle*, in a notice of his career, says: "We do not think that any other mayo of the present generation did such signal service to the city as Dr. Blackett, for it was mainly and in a very large degree owing to his efforts that the railway extension from Sunderland to Durham Elvet was brought to a successful issue."

Newcastle-upon-Tyne, Nov. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Medico-Chirurgical Society.

THE opening meeting of this society for the winter was held on Wednesday of last week. A few patients and specimens were shown, and thereafter the valedictory address of the President, Dr. Clouston, was read by the Secretary. Dr. Clouston, although recovering, is still forbidden to perform any public duties. An abstract of the address and account of the meeting is given elsewhere. Dr. Argyll Robertson was elected President, in succession to Dr. Clouston; Dr. James Carmichael was elected a Vice-president; and Dr. Graham Brown was appointed Secretary to succeed Dr. Gibson, who resigned; Dr. Hodsdon was reappointed Senior Secretary, and Dr. McKenzie Johnston Treasurer.

Glasgow Pathological and Clinical Society.

At the November meeting of this society the following cases and specimens were submitted. Two children the subjects of sporadic cretinism, one of whom had greatly improved under treatment by thyroid extract, as was evident by comparing photographs of her original condition with her present appearance, were shown by Dr. G. S. Middleton and Dr. R. Barclay Ness. Dr. Finlayson gave an account of a case in which cancer of the lung had been followed by enormous secondary developments in the liver, which weighed nearly twenty pounds; specimens from the case were submitted to the society. Dr. Ebenezer Duncan showed the thoracic viscera from a case in which pericarditis had been associated with pleurisy and thrombosis in the left subclavian vein.

Glasgow University.

The autumn graduation ceremony took place on the 8th inst. Amongst the graduands were twenty-four gentlemen who received the degrees of M.B. and C.M., and ten the higher degree of M.D. Amongst the latter the following were awarded "commendation": Geo. H. Edington, M.B., C.M. (thesis: Bile Salts in relation to the Excretion of Urea); A. Davies Hughes, M.B., C.M. (thesis: Anchylostomiasis); and Hamilton C. Marr (thesis: Myxœdema and the Functions of the Thyroid Gland, with notes on the Treatment of certain Cases of Insanity by Thyroid Preparations).—At the inaugural meeting of the Queen Margaret Medical Club Professor McKendrick demonstrated a series of experiments in Acoustics, the members meeting for this purpose in the physiological laboratory.

New Nursing Homes.

The Royal Scottish Nursing Association has established a branch at Dumfries.—The honorary presidency of the newly-formed nursing association for the Irvine district has been accepted by the Countess of Eglinton and Winton.

Defying the Medicine Stamp Act.

A chemist and druggist in Glasgow has, at the instance of the Inland Revenue authorities, been fined £42 for selling "corn solvent" without a Government stamp on the package. The same individual was on a former occasion penalised to the extent of £70 for a similar offence.

Nov. 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dublin University Election.

MR. LECKY, who is one of the candidates for the Parliamentary representation of the University, has written asking for information in reference to the grievances of the Irish Poor-law medical officers. Sir William Stokes, a past-president of the Irish Medical Association, stated in his reply that so far as the medical profession went there was a practical unanimity on the subject, especially as to the desirability of establishing retiring allowances or pensions for those members of the service who were incapacitated from doing their work by age or infirmity. After considering the matter Mr. Lecky has declared himself in favour of the proposed remedial legislation. "I fully recognise," he says, "the grievance, and shall be glad if I can do anything towards procuring retiring pensions for old and incapacitated Poor-law medical officers, and generally remedying any grievance under which Irish medical men may labour."[1]

Sir W. Thornley Stoker.

The dinner which was given by about 150 of the professional friends of the President of the Royal College of Surgeons of Ireland was held at the College on Nov. 2nd, and proved a very great success. The use of the large hall of the College was specially voted by the Council for the purpose, but proved insufficient to accommodate the large number of medical men who wished to avail themselves of the opportunity of congratulating the President on his receipt of the honour of knighthood.

Notification of Infectious Disease.

The case of Mason *v.* Hadden is again at hearing in the Exchequer Division, before the Lord Chief Baron and Mr. Justice Andrews. An application is now being made on the part of Dr. Hadden for an order to set aside the former verdict, by which the plaintiff was given damages of £100 for the alleged negligent treatment of a girl in his employment. The case is of great interest to the medical profession, and the result of the appeal will probably have far-reaching consequences.

Hospital Sunday in Dublin.

Last Sunday, Nov. 10th, was Hospital Sunday in Dublin, and eloquent sermons were preached in many of the churches in the city. In the Chapel Royal an anthem, composed for the occasion by Dr. Culwick, was sung by an augmented choir, while the sermon in aid of the collection was preached by the Dean. The returns have not yet been made out, but it is feared the inclement weather of Sunday may seriously and injuriously affect them.

The Private Hospital Case.

This case, which caused so much interest in Dublin some months ago, has been again at hearing during the past week in the Appeal Court, before the Lord Chief Justice, Lord Justice Fitzgibbon, and Lord Justice Walker. An attempt is now being made to set aside the order made by the Vice-Chancellor in April, granting an injunction by which the defendants have been restrained from carrying on the business of a private hospital in the house, 28, Fitzwilliam-square. The case is still being argued.

Application of the Sixty-five Years of Age Rule to Queen's College Professors.

A remarkable development of the attempt to apply the age limit to presidents and professors of the Queen's Colleges has taken place. Your readers are aware that the first step on the part of the Government was to inform the authorities of the Colleges that for the purpose of applying the rule the Colleges would be regarded as departments of the Civil Service, and that presidents and those of the professors whose incomes were over £350 a year should resign on reaching the age of sixty-five, unless it could be shown that their retirement would be prejudicial to the public service, and that in any case they should retire absolutely at the age of seventy. This innovation was strenuously and for the time being successfully opposed. President Moffett of Galway was compulsorily retired, but owing to the strong representations made the late Government referred the whole question to the Lord Chancellor of England. His decision was in favour of the

[1] The letter itself will be found in another column.—ED. L.

Digitized by Google

contention of the Colleges, and President Moffett was duly reinstated. So pleased were the students and people of Galway at the result that they turned out in large numbers and gave President Moffett a royal welcome on his return to the College. Meantime the Treasury officials would seem to have been occupied devising means for ignoring the charters of the Colleges with regard to all future appointments, and whilst the controversy was occupying public attention all new arts professors appointed received warrants in which a clause was inserted requiring them to retire at sixty-five years of age if called on to do so, and even as good terms were not meted out to new medical professors. They were simply appointed for seven years and would have to take chance as to whether they would be re-appointed at the end of that period. Not satisfied with those arrangements, the Government issued a departmental commission, consisting of Lord Playfair, Lord Welby, and Sir Mathew White Ridley, "to consider the desirability of a fixed age for the compulsory retirement of professors serving under the Crown." The commissioners reported: "We are of opinion that when a professor reaches sixty-five years of age the president of the College should be bound to report to the Government the condition and efficiency of the teaching. If these are and continue to be satisfactory, the professor need not be superannuated till seventy, but at this age his retirement should be absolute." Some of the witnesses urged on the commissioners the importance of all the medical professors being granted pensions on the same terms as the arts professors, but the commissioners urged that they could not entertain that matter, as it did not come within the scope of their inquiry. As the result of the report of the commissioners the Lord-Lieutenant has communicated to the three colleges his intention of altering the statutes of colleges so as to adopt the recommendation of the commissioners quoted above. I believe it is the intention of the professors of the colleges to send a deputation to his Excellency on the subject, for the purpose of pointing out how hostile to the interests of the colleges the proposed changes must prove to be. The great majority of the professors hold their appointments "at the pleasure of Her Majesty," a phrase which has always been interpreted as meaning that a professor could hold office as long as he is capable of discharging his duties efficiently. The professors rightly think the Crown ought to show a good example to the subjects of these realms by observing solemn contracts of the kind. But what can be said with regard to those of the medical professors who, owing to their being allowed to take private practice, are not entitled to pensions? Are the contracts with them not only to be broken, but are they to be dismissed at a definite age without any recompense whatsoever? Such treatment of a rural postman would be condemned by the public, and it is to be hoped public opinion will equally condemn any attempt at doing an injustice to the medical professors of our colleges.

The Prescribing of Medicines by Druggists.

At an inquest held in Belfast on Nov. 5th in reference to the death of a child aged two years it came out in the evidence that the mother, finding the child was suffering from whooping-cough, asked a druggist for something to relieve the cough. He gave her a bottle and told her to put flannel and wadding on the child and to take it to a medical man. She was to rub the contents of the bottle on the child's chest, which she did. The father of the child, in his evidence, said the druggist told him he would not prescribe for the child, and that the whooping-cough would have to take its course. The child was not taken to any medical man. The coroner, in summing up, said he would report the case to the Attorney-General or the Commissioner of Police and allow them to investigate the matter. He commented on the action of druggists in the city, who were not properly qualified, prescribing medicine, and he thought the Act of Parliament with reference to the matter was a dead letter as far as Belfast was concerned, and he considered that those who should see that the Aot was carried out were neglecting their duty. In their verdict the jury strongly condemned the action of any chemist, druggist, or other persons prescribing medicines for the sick poor. At the opening meeting of the Ulster Medical Society, on Nov. 7th, attention was drawn to the above remarks of the coroner, who has always shown himself most friendly to the medical profession, and it was unanimously decided to refer to the council of the Society the consideration of this growing evil of prescribing and advertising druggists in Belfast. The Council is to bring up a report at a future date before the society, when it is certain that the whole subject will be fully discussed.

The Treatment of Rabies.

The Newry guardians having sent some persons to a man named McGovern for treatment (they having been bitten by rabid dogs), the Local Government Board have written pointing out that McGovern's residence is not a hospital within the meaning of Section 7 of the Act 25 and 26 Vict., cap. 83. If any expenditure from the union rates is contemplated with cases of persons bitten by a rabid animal an extraordinary meeting of the guardians will have to be summoned. It was finally decided by the board of Newry guardians not to pay McGovern's bill until it should be seen how the patients got on.

The Ulster Medical Society.

The first meeting of the Ulster Medical Society for the session 1895-96 was held on Nov. 7th, when the incoming president, Professor Sinclair, F.R.C.S., delivered before a crowded audience of the profession his inaugural address. After thanking the members for the great honour they had done him, all the more appreciated by him as it was unanimous, Professor Sinclair took as his subject the relationship between medicine and surgery in diseases of the Chlyo-poietic Viscera. He discussed the treatment of ulcer, dilatation, and cancer of the stomach, diseases of the intestines, appendicitis, &c., and gave a most judicious, suggestive, and practical address. At its termination he was awarded a very hearty vote of thanks, proposed by Dr. McKeown, and seconded by Professor Byers. The council have decided to hold the annual dinner on Nov. 28th, when it is expected there will be a very large attendance.

The Night Nursing in the Lisburn Workhouse.

An inquest was held in the Lisburn Workhouse on Nov. 11th in reference to the death of a man aged fifty, who was found dead in his bed on the morning of Nov. 10th. He had been sent into the infirmary by Dr. Alexander of Knocknadona Dispensary, suffering from intestinal obstruction. He arrived between three and four o'clock P.M. on the 9th, and was seen by the nurses in charge at different times, but the medical attendant at the workhouse was not sent for. It came out in the evidence that there is only one night nurse, who is about sixty years of age, and she has charge of seven wards containing between sixty and seventy patients. The jury added a rider to their verdict calling the attention of the board of guardians to the inadequacy of the night nursing. Dr. Mackenzie (medical attendant of the workhouse) said that before his appointment there was no night nurse. The present night nurse came to the workhouse as a scrubber, and he recommended the guardians to appoint her, but he could not say he looked upon her as a competent nurse, and he thought the jurors were quite justified in appending the rider they did.

Royal Hospital Sunday.

At a special meeting of the clergy it was decided that the second Sunday in February be Hospital Sunday for the time to come in Belfast. There are in the city of Belfast 138 congregations, and only 58 of these made a collection for the Hospital last year. It is hoped many more, if not all, will make a collection this year.

Nov. 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Foreign Practitioners in Paris.

FROM an analysis of the last census, published recently by M. Bertillon, it appears that the profession that attracts the most foreign votaries to Paris is that of medicine. There are, in fact, established in this city no fewer than 521 foreign medical men. This figure constitutes rather more than a sixth of the total number (2922) of Paris practitioners. The number of foreign residents in Paris being 180,000, the proportion of foreign medical men to foreigners is about 3 per 1000, whereas that of French practitioners to the strictly Parisian population is only 1 per 1000.

A Monument to Pasteur.

The administrative council of the Pasteur Institute, at a recent meeting, presided over by M. Bertrand, Permanent Secretary of the Académie des Sciences, decided to appoint a subscription committee, with a view to the erection of an international monument to perpetuate the memory of Louis Pasteur.

Medical Ministers.

In this land of political instability, where a Cabinet Minister may awake and find himself one fine morning suddenly relegated to the enjoyment and freedom of private life, it is perhaps gratifying to find that our French *confrères* who mix in politics frequently advance themselves into the front rank. Thus in the Ribot Ministry, lately defunct, there were two members who could write M.D. after their names. The present Ministry also has two medical men in its ranks—viz., Dr. Viger and Dr. Combes. Dr. Viger is, indeed, becoming quite "an old Parliamentary hand," having already exercised twice his present functions of Minister of Agriculture. He is, I believe, a most competent authority on things agricultural, and his energy in visiting country districts must be highly appreciated by farmers. Dr. Combes, when the Ministry was in the first throes of construction, held for a few hours only the portfolio of Public Works; but he has since assumed the duties of Minister of Public Instruction. We may almost count M. Berthelot, the eminent chemist, and now Minister of Foreign Affairs, as one of our own body. In the last Ministry of which he was a member he was a Minister of Public Instruction. By the way, Caran d'Ache has a most amusing series of caricatures in one of the daily papers. In them are illustrated in his usual comic manner the contortions of various foreign diplomats at a dinner given by the new Foreign Minister. The last caricature supplies an explanation of the horrible sufferings of the guests. M. Berthelot's cook had unwittingly made use for culinary purposes of pans, &c., that had been until quite recently doing duty in his eminent master's chemical laboratory.

Experimental Congenital Malformations.

MM. Charrin and Gley[1] have for the last five years been conducting in the country a series of experiments calculated to throw light on the influences of viruses on the offspring of the recipients. The experiments have been varied in such a way that either the male and female have been inoculated with the bacillus of blue pus or of its toxines, or only one of the animals has been inoculated. The results have not been uniform; most frequently there ensues sterility, abortion, or the birth of progeny that dies immediately. In rare instances the offspring survive; more rarely still they are healthy. Until recently fœtal deformities have not been noted, although certain rabbits born in these conditions remained dwarfed, and the bones of these undeveloped animals were provided with enormous epiphyses, the diaphyses being shortened. MM. Charrin and Gley are now, however, able to speak with authority on the malformatory power of cultures. They showed two rabbits born of a couple of which the male alone had received inoculations of sterilised cultures. Five rabbits were born, of which two were normal, and a third, whose ears were rudimentary, died in a few days. In the remaining two now shown to the Academy the ears comprised only fragments with jagged upper edges; the tails are only 2 centimetres long; the external orifice of the vagina (one rabbit is a male and the other a female) is oblique; and one of the limbs, the hinder in the male and the fore in the female, is much shorter than its fellow, the difference being 4 centimetres. The shortened limb ends in a kind of stump, there being no proper foot or toes. It is interesting to notice the analogy between the degenerative effects of these cultures and the syphilitic virus, even when only the male progenitor is under its influence. The experiments go to prove that there is no special transmitted influence inherent in the virus of syphilis, seeing that other poisons have identical effects on the offspring. The experiments further elucidate the problem of heredity, and demonstrates the influence on the progeny of the modified cell, whose attributes are thus transmitted to the next generation.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Admission of Women to Medical Examinations

ACCORDING to an article by Mrs. Bluhm, M.D., published in the *Deutsche Medicinische Wochenschrift*, there are only seven female medical practitioners in the whole German Empire, of whom four are in Berlin and one respectively in Munich, Leipsic, and Frankfort. Some of the ladies are in good practice. They are, however, not permitted to take German degrees, but they have to go abroad—usually to Switzerland—for the purpose of graduation. From a legal point of view their diploma is of no value, and they are nominally unqualified, but they are nevertheless allowed to attend patients, as unqualified practitioners are not interfered with unless they pretend that they are in possession of legal diplomas. As I explained in my article on "Medical Study in Germany," which appeared in THE LANCET of Sept. 14th, 1895, it is only pupils of the gymnasia who are allowed to become medical students; and before going to a university they have to pass the *Abiturienten-Examen*. Hitherto there has been no gymnasium for females, and therefore the university portals have been closed to all ladies who could not afford to go abroad. A gymnasium for females has, however, now been established by private means in Berlin, and possibly its pupils will be allowed to pass the prescribed *Abiturienten-Examen*. Moreover, by special order of the Minister of Public Instruction a young lady who applied for examination at the Liegnitz gymnasium has lately been admitted, and she will probably be the first recognised female medical student in this country. During last Parliamentary session the same Minister stated that the Government was considering the conditions under which ladies could enter on an academical career, and the advocates of the higher education of women are accordingly full of hope.

Poisoning by Phenylhydroxylamine.

The following case is described in the *Deutsche Medicinische Wochenschrift* of Oct. 14th by Dr. Hirsch and Dr. Edel, physicians to the Municipal Hospital of Charlottenburg, Berlin. A student of the technical academy, while working in the chemical laboratory, broke a bottle containing an alcoholic solution of phenylhydroxylamine (C_6H_5NHOH), which saturated his clothes and flowed over his abdomen and the inner side of his thigh. He felt at once an intense burning of the skin and retired to the lavatory to apply a cold-water bandage. About fifteen minutes afterwards he was found there in an almost helpless condition, being comatose and pulseless, with stertorous respiration and no reflexes of the cornea or pupils. When he was brought to the hospital the physicians believed him at first to be moribund. The alteration in the colour of the skin was very singular. The lips and mucous membrane of the mouth were greyish-blue, and the skin of the extremities was of an intense blue colour, which contrasted peculiarly with the cadaverous aspect of the other regions. There were also numerous reddish-brown spots on the hands, thighs, and abdomen, which did not disappear on pressure with the finger. Respiration was deep and regular, but the cardiac action was extremely weak. Injections of camphor, a hot bath, and other excitants having no visible effect, venesection was performed, and 300 c.c. of dark-brown, chocolate-like blood were drawn off. An intravenous injection of one litre of a solution containing 0·3 per cent. chloride of potassium and 0·4 per cent. bicarbonate of potassium was given immediately afterwards, whereupon the pulse and respiration rapidly improved, and the patient in course of time regained consciousness. He vomited a large quantity of brown-coloured mucous fluid. During the first hours no urine was passed, and the catheter had to be used; the urine thus evacuated contained much albumin and a rather large quantity of casts. During the first day the skin retained its peculiar colour. The patient passed a comfortable night, and on the following day, though still very weak, he felt quite well. The pulse became better, the urine was voided spontaneously, and the albumin and casts disappeared on the following day. The lips were now of a pale-rose colour, the skin was very pale, and on the third day the normal aspect was restored. The patient soon recovered and was able to leave the hospital. Microscopical examination of the blood proved that the form of the red blood-corpuscles was not changed, but that the hæmoglobin had almost completely left them, and the spectroscope showed that the hæmoglobin was altered into methæmoglobin, to which was due the brown colour alike of the blood, the vomited matter, and the little spots on the skin. The case is very like one of poisoning by nitrobenzol, from which phenylhydroxylamine is derived. The alterations of the colour are characteristic of both drugs, but nitrobenzol never acts as quickly as the other. In the cases of nitrobenzol poisoning hitherto described the full toxic action

Digitized by Google

did not appear before one or two hours; but in the present case the patient was in a helpless state in fifteen minutes, the poison having been absorbed by the skin only and not by the stomach. The characteristic smell of oil of bitter almonds was also absent. Phenylhydroxylamine is, therefore, a violent poison, which rapidly acts on the blood, the heart, and the kidneys.

New Regulations for Private Lunatic Asylums.

The irregularities in private lunatic asylums which were disclosed by the Mellage trial, mentioned in THE LANCET of June 15th, 1895, and some other serious charges made by the lay press against these institutions, have induced the Government to issue new regulations, the principal feature of which is that no patient may be received into an asylum without a certificate from the medical officer of health of the district (Kreisphysicus). In cases of emergency any other physician may give this certificate, the district officer of health being informed of the fact within forty-eight hours, so that he may examine the case and decide whether the patient shall remain in the asylum or be released. Notice is also to be given to the district court of law in order that the formal "declaration of insanity" (Entmündigung) required by the civil law may be executed. For the release of violent lunatics the consent of the district medical officer is required, and he is responsible for his decision. No medical man may in future superintend an asylum unless he possesses a special knowledge of lunacy. In every asylum containing more than fifty patients a resident physician is to be appointed; if there are more than a hundred patients a second resident medical man is required. The proprietor of the asylum, if he is not himself a medical man, may not exercise any authority in medical questions. Asylums are to be inspected without previous notice twice a year by the district officer of health, and once a year by the Visiting Commission, consisting of medical men and lawyers. It is doubtful whether public uneasiness will be allayed by these regulations, for some of the most serious charges were made not against private but against public asylums, and to these the regulations do not extend.

Attempted Murder of a Medical Officer by a Lunatic.

Dr. Schäfer, chief medical officer of the provincial lunatic asylum at Lengerich, Hanover, was recently, during his morning visit, attacked in the wards by a patient and seriously wounded in the neck with a knife. It is not yet certain if Dr. Schäfer's life will be saved.

Nov. 13th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Red Cross Extension.

RATHER more than two years ago a Congrès International de Samaritains was in contemplation with the object of extending to civil calamities the organisation and resources of the Red Cross for military ones. The project had many sympathisers and supporters not only in the lay but in the professional journals. THE LANCET of Sept. 2nd, 1893, took part in the discussion and asked very reasonably: "Is it only in war that men are injured *en masse*, that human life is endangered so as to require immediate succour on an unforeseen scale, that villages and even towns are visited by disaster, social as well as physical, that in a night or in an hour whole populations may be made homeless or subjected to frightful privations? Are there no such things as mining accidents, as earthquakes, as inundations, as famines, as epidemics, as long-continued cold or heat, or conflagrations, or the thousand and one casualties by which the one-half of a city or countryside may be suddenly thrown on the active sympathies and benevolent aid of the other?" To such questions the answer was all too immediate, but the mode of meeting the situation they pointed to was not so easily settled. The utilisation of the Red Cross Societies, local and central, at first seemed a ready way out of the difficulty, but the proposal was met by the determined opposition of the magnates of the Red Cross itself—nowhere more than at its headquarters in Geneva. The civil communities, they practically said, must look after their own "wounded" and expect no reciprocity of aid from a service which is constituted solely to mitigate the horrors of war. So effective was this opposition that the contemplated Congress, whose seat was to have been Vienna, never met at all; but, nevertheless, the discussion which grew out of the proposal was not without its fruits. Italy, which justly claims priority in the conception, if not the actuation, of the Red Cross, had already taken the initiative in the direction desiderated; and her White Cross, instituted tentatively some seven years before, assumed fresh life and energy from the renewed ventilation of "How to relieve the sufferers in that social warfare ever waged between man and circumstance." Some account of the development of this movement, particularly in Upper Italy, was given in these columns as recently as Oct. 19th, and to-day I have to add a further indication of the vitality it is exhibiting. This month, in Rome herself, there has been opened an "arruolamento" (enrolment) of fifty "volontari sanitari" for service under the White Cross, subject to the conditions laid down in the "Statuto" of the society. After an "alunnato" (pupilage) of six months these sanitary volunteers will be entitled to enrolment in the effective "Corpo dei Volontari," and will enjoy all the rights of the society, including those of the "Cassa di Previdenza" (mutual relief fund). The uniform of the volunteers, an effective garb of cloth and linen (*panno e tela*), is furnished gratuitously from headquarters, and a number of privileges are attached to the service, which, besides its humanitarian attractions, must tend to recruit its ranks from honourably aspiring citizens. Full particulars of the organisation and objects of the White Cross, for all who are interested in the movement, may be obtained from the Secretary, at the society's headquarters in Rome, Via delle Zoccolette, No. 62.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Russian Medical Societies.

THE number of medical societies in Russia is considerable, and is constantly being added to. Seven years ago there were only 80 such societies, now they number some 120. There is scarcely a town of any size or importance which does not possess one at least. In Moscow there are eleven; in St. Petersburg sixteen; the Caucasus has its Imperial Caucasian Medical Society, founded in 1864 and meeting two or three times a month in Tiflis, as well as three lesser societies; the Terek Medical Society in Vladikavkaz (the capital of the Northern Caucasus) founded in 1891; the Medical Society in Kutais, a year younger; and the Society of Medical Practitioners in Baku, instituted only last year. Even Siberia possesses eight medical societies. The oldest of these, the Society of Medical Practitioners in Eastern Siberia, meeting in Irkutsk, dates from 1863, although it had existed unofficially for five years before that date. In 1864 the Physico-Medical Society was formed in Tobolsk; eight years later the Society of Vladivostok Naval Surgeons came into existence; in 1883 the Omsk Medical Society; in 1886 the Society of Practitioners in the Yenisei Government, meeting in Krasnoyarsk; in 1889 the Society of Biologists and Medical Practitioners in the University of Tomsk; in 1892 the Society of Medical Practitioners in the South-Ussuri region, meeting in Vladivostok; and, finally, in the same year the Transbaikal Medical Society was inaugurated in far-away Tchita, close to the Mongolian borders. The oldest institution of the kind in European Russia is the Physico-Medical Society in the University of Moscow, dating from 1804. Only one year younger is the Imperial Vilna Medical Society, instituted when Vilna still possessed that University of which she was forcibly deprived later as a punishment for the part she took in the famous rebellion of 1833. Another Polish society, the Warsaw Medical Society, can boast a respectable age, dating back to the year 1821. In St. Petersburg the oldest is the German Medical Society, the Deutscher Aërztlicher Verein, formed in 1819. Last session this society had but 6 honorary and 25 ordinary members. Many times larger is the Society of Russian Medical Practitioners, numbering 70 honorary and 230 ordinary members, founded in 1833, and now under the presidency of Professor Popof. This, it may be noted in passing, is one of the very few medical or other learned societies whose date of foundation falls within the thirty years of the Emperor Nicholas's reign (1825-56). During that reactionary period all intellectual initiative was sternly discouraged. Only two other medical societies—

Digitized by Google

one in Kief (1840) and one in Odessa (1849)—date from his reign. The failure of the Crimean War and the death of Nicholas were followed by a revival of intellectual activity and freedom of thought. A number of medical societies still existing were founded in the late fifties and early sixties. Of these may be mentioned the Society of Naval Surgeons in St. Petersburg, instituted in 1858; similar societies in Cronstadt and Nikolaef in 1859; the St. Petersburg Society of Medical Practitioners and the Society of Russian practitioners in Moscow in the same year; and societies founded in Nijni-Novgorod, Kharkof, and Yaroslav in 1861; in Tula and Kursk in 1862; in Archangel, Mogilef, and Orel in 1863; and in fifteen other towns between the last-named date and 1870. Many of these early societies had dispensaries attached to them for the free treatment of the poor, and were quite as much philanthropic institutions as learned societies. This is the case even to the present day with some Russian medical societies. Two other peculiarities of, at least, some Russian societies are worth mention: these are the admission of the lay public to the meetings, and the appearance in the lay press of reports of the societies' discussions. The advantage, or propriety, of these practices is strongly questioned by some members, even of societies in which they prevail. The annual subscription to Russian medical societies varies considerably—the lowest is 3 roubles,[1] the highest (that of the Moscow Surgical Society) is 25 roubles; either 5 or 10 roubles is the usual subscription. Almost all Russian medical societies publish their Transactions (*Protokolui* or *Trudui*) annually, or more often in paper-covered volumes.

Prevalence of Infectious Disease in St. Petersburg.

There has been an unusual prevalence of zymotic disease in St. Petersburg during the past few weeks. The municipal authorities have hospital accommodation for 2570 patients, but at the present moment they have no less than 3258 cases on their hands, of which some 1500 are said to be suffering from typhoid fever. Scarlet fever and diphtheria are also unusually prevalent. To provide for the excessive influx of patients the authorities have converted an unoccupied building which was at their disposal into a temporary hospital, to which cases of more or less chronic character have been removed.

The Force of Example in Suicide.

The "infectiousness" of certain forms of suicide is well known, and has been curiously illustrated recently in this city. In the month of September three young girls threw themselves from high windows on to the pavement intending to kill themselves. It is a remarkable fact that though one threw herself from the third storey, one from the fourth, and one from the fifth, all have recovered from their injuries. These were naturally severe, including fractures of the wrists, legs, and jaw and concussion of the brain. The youngest of the would-be suicides was aged twelve and the eldest nineteen.

The Proposed Changes in the Russian M.D. Degree.

With regard to the proposed changes in the Russian M.D. degree, the statement in my last letter[2] that the Medical Council had decided to make those changes was rather premature. No final decision has yet been come to, and the scheme has been again referred to the Army Medical Academy, who will discuss it at a meeting to be held to-morrow.

St. Petersburg, Oct. 27th (Nov. 8th).

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera News.

THE daily bulletin of yesterday gives the whole number of cases since the beginning of the outbreak as 584, and of these no less than 443 died. Since yesterday there have been 24 new cases to be added to 65 already under medical care, and 24 cases have died in the various ambulance hospitals, besides 28 deaths in private houses. News from some of the districts takes two or three days to reach Cairo, because of the absence of telegraphs. The cholera is still entirely confined to Damietta and to one neighbouring village, and to the province of Dakahlieh, in which there are several infected villages. The disease has not spread to the large towns in the vicinity, and the nearest distance from any infected area to Cairo is about 100 miles, or at least twelve hours by express train and steamer. I specially mention this because letters and telegrams are constantly arriving from England asking whether the cholera still exists and whether visitors may safely arrive. The disease, since it was first taken seriously in hand, has shown no tendency to spread during the last fortnight, and the increase in the number of cases is entirely due to the energy of the English medical men on the spot, who are searching out every possible case. In times of epidemic it is obvious that many deaths from ordinary causes are reckoned as cholera, but, on the other hand, the slight cases of the disease are not recognised, and therefore do not go to swell the statistics. It is obviously better that too many, rather than too few, of the doubtful cases should be officially returned as cholera. All observers agree that this outbreak, both clinically and bacteriologically viewed, is remarkably mild, and, in view of the energetic means taken for stamping it out, it must shortly cease to exist from lack of material. So long as it continues to slumber and to make no headway against the abundant and pure water-supply, and so long as it continues to be confined to its present localised area, where only the poorest inhabitants furnish victims, I see no reason why European and American visitors should not carry out their intention of coming to Egypt. The general health of Cairo and of the rest of Egypt, as shown by the death returns, was rather better last month than in the month of October of previous years. The resident families are all returning from Europe, and a considerable number of tourists have already arrived.

Cairo, Nov. 6th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Antitoxin as a Preventive of Diphtheria.

THE report of the New York Board of Health on the treatment of diphtheria with antitoxin, just published, covers the first nine months of the present year and the corresponding portions of the four preceding years. In 1895 antitoxin has been manufactured in the department's laboratory and has been extensively, though by no means universally, used as a remedy for the disease. In the preceding years it was, of course, not used. Statistics in the report show that in the four years before the introduction of antitoxin the percentage of cases of diphtheria terminating fatally ranged from 30·67 to 37·34, and averaged 34·63, while in 1895, under partial treatment with antitoxin, it fell to 19·43. That is, there was a reduction of the death-rate by 43·94 per cent. Had antitoxin been used, therefore, in the four preceding years with such effect as in 1895, more than 3000 lives would have been saved. A peculiar feature of the report is its statement of the enormous increase in the number of cases of diphtheria—or of diphtheria and croup, for the report covers both—during the last two years. In 1891 there were 3686, in 1892 4156, and in 1893 4721. The last was the largest number up to that date and showed the highest death-rate—viz., 37·34 per cent.; but in 1894, when antitoxin was being experimentally used, the number of cases rose to 7446, and the death-rate fell to 30·67, and in 1895, with the new remedy extensively administered, the number of cases rose still further to 7921, and the death-rate fell to 19·43. The only explanation of this would seem to be that since the introduction of antitoxin a great many children suffering from light and trifling attacks have been treated and reported as suffering from actual diphtheria. They have recovered as they would have done without antitoxin and thus have given that remedy credit which it does not deserve. This view is strengthened by the fact that the actual number of deaths during nine months of 1895 has been 1643, or only a trifle less than the average of the four preceding years, which was 1734.

Sanitary Management of Cholera in Japan.

A New York reporter gives the following account of the management of an outbreak of cholera in a village of Japan by the sanitary police. A large plain box lined with zinc was brought. The body was hastily placed in it, a liberal supply of quicklime was pitched in, the lid was screwed

[1] A rouble is equivalent to rather more than 2*s*.
[2] THE LANCET, Oct. 26th, 1895.

Digitized by Google

down, and away the cart and its load went. Meantime disinfectants had been brought up. The poor wife and three children were divested of their scant clothing, hurriedly washed with some anti-microbe preparation, wrapped in fresh cotton kiminos, and sent to a place of care and detention in the neighbourhood. The work of burning every particle of clothing and bedding and matting then began in the back-yard, a bonfire being made for the purpose. Every particle of excrementory matter on the premises was thrown upon this blazing pile. Then the whole premises were thoroughly saturated with disinfectants of the most approved character, the house was closed, and a policeman was left in charge to keep the people off the premises. The officer in charge stated that if the epidemic had been showing a disposition to increase this house would have been burned to the ground. The scant furniture and belongings of a Japanese house of the poorer class enable the police to carry out their regulations at no very great cost. The latest figures officially touching cholera in Japan place the total number of cases to date at 48,129, and the total number of deaths at 32,848.

Report on Vivisection.

At a recent meeting of the American Humane Association there was a report of a medical committee which for several months has been engaged in sounding public sentiment in regard to vivisection. Over 2000 expressions of opinion were obtained from leading physicians, teachers in medical colleges, authors, clergymen, college professors, and presidents. Of these only about one-eighth were in favour of unrestricted experimentation upon living animals, the large majority being for absolute prohibition, or for such restrictions by law as should limit vivisection to painless operations or those having a definite relation to the treatment of human ailments. A preponderance of sentiment appeared to be favourable to a statement of opinion which declared "that only a great and definite advantage to the interests of humanity can justify vivisection at all," and which condemned as cruel and wrong "the infliction of torment upon living animals, simply to illustrate well-known physiological facts, or as a method of research into curious physiological phenomena which have no conceivable relation to the cure or treatment of disease."

Important Order of Government in relation to the Exportation of Meats.

The Secretary of the Interior has issued the following order:—"It is ordered that from and after Sept. 16th, 1895, all beef offered for exportation, whether fresh, salted, or canned, corned or packed, shall be accompanied by a certificate showing that the cattle from which it was produced were found free from disease, and the meat sound and wholesome, by an inspector of this department. And in order that it may be determined whether all beef exported has been so inspected and found to be sound and wholesome it is further ordered that the meat of all other species of animals, which for any reason does not bear the inspection tags and stamps of this department, shall be packed in barrels, cases, or other packages, which are legibly marked in such a manner as to clearly indicate the species of animal from which the meat was produced. Meat which is not so marked, and which is not accompanied by a certificate of inspection, will be classed as uninspected beef, and will not be allowed exportation. Notice is hereby given to all exporters of meat, whether said meat is fresh, salted, corned, packed, or otherwise prepared, and to owners and agents of vessels upon which said meat is exported, that no clearance can be given to any vessel having on board said meat until the provisions of this order are complied with."

Oct. 26th.

FOOTBALL CASUALTIES.—Last week the following accidents occurred:—In a match, at Chichester, between two local junior clubs, the left forward of one of the teams fractured his left clavicle. While playing against the Weston-super-Mare team, the Bristol wing three-quarters fractured his nasal cartilage. During a game, at Langton, Staffordshire, a youth received injuries from which he died a few days later. In a match between the Addlestone and Guildford Reserve teams, the Guildford goalkeeper dislocated his humerus. On Saturday last, while playing in a Scottish League match at Greenock, the Renton Club centre half-back fractured his leg. A similar accident occurred to the right wing forward of Motherwell, and in another match a player of the Linthouse team fractured his clavicle.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on the 14th inst., the President, Mr. Christopher Heath, being in the chair.

The PRESIDENT reported to the Council the proceedings at the annual meeting of the Fellows and Members, and stated that in addition to eighteen Members of the Council there were present forty-six Fellows and seventy-eight Members.

The consideration of the resolutions in favour of an Amended Charter was deferred.

The Council proceeded to the further consideration of the Memorial from the London School of Medicine for Women, and it was resolved that—

"The Council of the Royal College of Surgeons of England, although in favour of granting the petition of the officers and teachers of the London School of Medicine for Women, do not see their way to admit women to the Conjoint Examination in face of the adverse vote of the meeting of the Fellows and Members of this College and the expressed opinion of the Royal College of Physicians."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination in Anatomy and Physiology for the Diploma of Fellow at a meeting of the Board of Examiners on Monday, Nov. 11th, viz.:—

Henry Brunton Angus, L.R.C.P. Lond., M.R.C.S. Eng., University of Durham College of Medicine; Albert Edwin Hayward Finch, L.R.C.P. Lond., M.R.C.S. Eng., and Henry Talbot Sidney Areline, L.R.C.P. Lond., M.R.C.S. Eng., University College, Bristol; Robert Forsyth, M.B., R.U.I., Queen's College, Belfast, and Owens College, Manchester; Joseph Faulkner Dobson, Yorkshire College, Leeds; Herbert Alexander Bruce, Toronto University; and Howard Henry Congreve Dent, Masons College, Birmingham and St. Bartholomew's Hospital.

Thirteen gentlemen were referred for six months.

Tuesday, Nov. 12th:—

Albert Paling, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng., and Frank Mannington, Middlesex Hospital; Robert Earle Newton, M.B., M.S. Glasgow, L.R.C.P. Lond., M.R.C.S. Eng., Glasgow University and St. Bartholomew's Hospital; James Batterby, St. Mungo's College, Glasgow; John Mooney, Owens College, Manchester; James Midleton Graham Swainson, Westminster Hospital; Percy Edgar Tresidder, L.R.C.P. Lond., M.R.C.S. Eng., Guy's Hospital; and Evan Richard Frazer, London Hospital and Oxford University.

Twelve gentlemen were referred for six months.

Wednesday, Nov. 13th:—

Edwin Gilbert Emerson Arnold, L.R.C.P. Lond., M.R.C.S. Eng., St. Thomas's Hospital and Durham University; Cyril Wace, L.R.C.P. Lond., M.R.C.S. Eng., and Robert Macnamara Cowie, King's College, London; Harold Wilson Bruce, William Tayler Milton, Ferdinand Stanley Batchelor, Guy's Hospital; Thomas Caldwell Litler Jones, William Joshua Harding, and Egbert Coleby Morland, St. Bartholomew's Hospital; John Edwin Ford Palser, London Hospital; and Reginald Cecil Bligh Wall, London Hospital and Oxford University.

Nine gentleman were referred for six months.

The following are the arrangements for the Final Fellowship, for which forty-two gentlemen have entered their names:—

Monday, 18th.—Written Examination, 1.30 to 5.30 P.M., at Examination Hall.
Tuesday, 19th.—Clinical Examination, 2.30 to about 6.30 P.M., at Examination Hall.
Wednesday, 20th.—Operations, 1.30 to about 6 P.M., at Examination Hall.
Tuesday, 21st.—Surgical Anatomy, 2 to 4 P.M., at Examination Hall.
Friday, 22nd.—*Vivâ voce* Examination, 5 to 9.15, at Royal College of Surgeons.
Candidates will be required to attend on each of the above-mentioned days.

THE Duke of Westminster has forwarded a cheque for £600 to the Chester Infirmary, the amount of fees paid by visitors for viewing Eaton Hall.

CHRIST'S HOSPITAL: PEEK'S PRIZE ESSAYS.—It will interest some of our readers to know that more than one hundred and twenty copies of the book, "The Christ's Hospital Controversy," have been applied for by intending competitors for these prize essays, recently advertised in our columns, and which are to be sent to Messrs. Causton and Sons, Eastcheap, before the end of the year.

UNIVERSITY OF OXFORD.—The Regius Professor of Medicine gives notice that both the examinations for the Degree of Bachelor of Medicine will commence at 10 A.M. on Friday, Dec. 6th, in the Examination Schools. The secretary to the Boards of Faculties will receive the names of candidates—either by letter or from the candidates in person—at his office in the Clarendon-building, Broad-street, at any time not later than 10.30 A.M. on Friday, Nov. 22nd.

THE BOROUGH HOSPITAL, BURTON.—The new Borough Hospital for Infectious Diseases, Burton, was formally opened on Nov. 6th by Mr. Parker, the Mayor. The site, which is freehold, contains an area of about nine acres, and is called Outwoods Hill Field, one of its sides forming the borough boundary. The buildings for the accommodation of patients comprise a scarlet fever pavilion and an isolation block. The former contains two wards, each 60 ft. long, 26 ft. wide, and 13 ft. high, providing space for ten beds, and having in addition a small room for a patient who may require separate accommodation. Twenty-two beds for scarlet fever are thus provided. The isolation block contains two wards of three beds each and two wards of two beds each, well isolated from each other, so that either cases of a doubtful nature or two different classes of infectious disease may be placed in them. The other buildings are (1) the administrative block, which is two storeys high, and contains the committee-room, dispensary, kitchen, linen room, and accommodation for the matron and nine nurses, besides the servants; (2) a block comprising the laundry, disinfecting room (with Washington Lyon's high-pressure steam apparatus), the mortuary, post-mortem room, &c.; (3) the discharged patients' bathroom; and (4) the entrance lodge. The Local Government Board has authorised the raising of a loan of £11,500, being the estimated cost of the nine acres of land and the buildings when finished.

THE SIXTH INTERNATIONAL VETERINARY CONGRESS.—The Sixth International Congress of Veterinary Surgeons was held at Bern, Switzerland, from Sept. 16th to the 21st, when some conclusions were arrived at with regard to animal diseases of a contagious kind, which have a particular importance now so much attention is directed to the subject. One of the subjects discussed was the necessity for instituting an international veterinary sanitary service and the publication of an international bulletin on the contagious diseases of the domestic animals. This was unanimously adopted. The employment of mallein in the diagnosis of glanders was considered, and it was decided by 49 votes against 39 that this substance is an excellent means for ascertaining the existence of the disease in suspected cases, and that its systematic application in infected stables is the best measure for ensuring the extinction of glanders. Professors Nocard and Bang proposed that as tuberculin is a valuable means for diagnosing the existence of tuberculosis in animals and may render the greatest service in combating that malady, its employment should not be abandoned on the pretext that it may aggravate it, this being adopted by a large majority, while another proposal by Professor Nocard, to the effect that Governments should prescribe the use of tuberculin in places where tuberculosis is present, was carried by 73 votes against 25. It was decided that preventive inoculation is an indispensable measure in the suppression of the destructive swine plague. With regard to the use of the flesh of animals affected with tuberculosis it was decided—(1) that measures should be adopted for controlling the issue of flesh derived from tuberculous animals, and that if such flesh be seized compensation ought to be made to the owners if they have submitted to the sanitary measures; (2) that seizure should take place when the tuberculous lesions, by their extent and their character, render the flesh dangerous (adopted by 89 against 8 votes); (3) that this flesh should not be sold if it is that of an emaciated animal, appears to be unhealthy, if the lesions extend to the muscles, or important lesions are found in several of the viscera; (4) that it is desirable that the flesh of tuberculous animals recognised as fit or consumption as food shall only be exposed for sale in special stalls and have a notification of its character, or shall have been submitted to efficient sterilisation; and (5) that the different Governments should favour as much as possible the institution of apparatus for sterilising flesh. It was also decided that the various countries officially represented should have their attention directed to the necessity of everywhere making general the inspection of meat. In connexion with the latter decision it was also accepted, by 80 votes against 8, that in each country there should be a commission appointed to determine precisely in what cases the abattoir inspectors shall allow to be sold or seize a portion or the whole of the carcase of an animal in which the existence of tuberculosis has been discovered on examination. In view of the unsatisfactory condition of veterinary anatomical nomenclature, the section of the congress detailed to give an opinion as to the necessary steps to be taken to remedy it, reported that the *Nomina Anatomica* of His be recognised as a basis for an international Latin nomenclature of veterinary anatomy, and that the work of adaptation, as well as the creation of new Latin denominations, should be allotted to certain anatomists of the countries represented, with the right of co-optation. This recommendation was unanimously adopted, and gentlemen were appointed to undertake this task, these being MM. Müller of Berlin, Arloing of Lyons, Lorge of Brussels, Sussdorf of Stuttgart, Schmalz of Berlin, Martin of Zürich, Rubeli of Bern, and Szakall of Pesth.

THE DIFFUSION OF SMALL-POX.—With the advent of autumnal weather the small-pox now for a long time endemic in London has not hitherto shown much disposition to spread, but in the two weeks ended with last Saturday there was some increase over recent preceding weeks, the cases removed to hospital having been 29 and 14, and thus more than the total of the three weeks preceding, wherein the removals had been severally 9, 7, and 14. The attacks were diffused over the weeks unequally; thus we hear of 4 cases one day, followed by none on the next day, then 6 and 5 on succeeding days, and so on. The total of cases remaining under treatment is, however, steadily declining. The number on Saturday last was only 78, a fall from 106 in one week, and from upwards of 200 in early October. There was 1 death registered in each of the two weeks on board the hospital ship *Atlas*, one being that of an unvaccinated girl who came from Battersea, and the other that of another unvaccinated girl aged twenty-four years who came from the Newington sanitary area. In the borough of West Ham there has of late been some amount of small-pox, the cases occurring there largely augmenting the admissions to the ships down the river, and in the two weeks under review there have been 2 deaths there. The number of defaulters in the district has largely increased during recent years, information now coming to hand showing that in two districts in the union there have been, in one 6191 defaulters under the Vaccination Acts in five years, and in another 2163 defaulters in less than two years. In Wiltshire there has been an outbreak of small-pox at Barford St. Martin, 3 cases occuring in two adjacent houses, the initial attack being in a woman who had been residing in Bristol, the infection being apparently carried to her neighbour, and later to his infant daughter. Two empty cottages, far removed from dwellings, were at once rented by the Wilton Rural District Council, and the patients removed thither, vaccination being enjoined on the public. In Derby the medical officer of health has just published a report on the two small-pox outbreaks of the present year, the 89 cases being divided into 62 vaccinated non-fatal cases, and 27 unvaccinated cases, with 8 fatalities, or just on 30 per cent. of attacks among the unvaccinated patients. The vaccinated cases remained on an average 31 days in hospital, and the unvaccinated 46, or more than a fortnight longer. The small-pox outbreak at Trawden has now subsided, there being at the beginning of this month only 3 patients in the hospital at Catlow. At Bacup a case has arisen in a young man, whose fellow lodger has been revaccinated and placed in quarantine; the patient himself has been isolated in the Sourhall hospital. During the last quarter there were in England and Wales 99 deaths from small-pox, of which 31 belonged to London, 17 to Oldham, and 21 to the West Riding of Yorkshire. In Ireland in the same period the deaths from small-pox, which had been 98 and 24 respectively in the two previous quarters, further fell to 14, and of these 12 were in the Dublin registration district. In the last two completed weeks of last month the admissions to Dublin hospitals had

Digitized by Google

been six in all, and there was one death—namely, that of an unvaccinated infant. On the several Saturdays of the four weeks ended with Oct. 26th the patients remaining under treatment were 27, 24, 24, and 18, and in the week next succeeding the admissions were 3, the discharges 4, and 1 death occurred (that of a vaccinated adult), leaving 16 cases in hospital, so that the disease, whilst still lingering in the city, makes no headway.

THE ALEXANDRA HOSPITAL AT RHYL.—A deputation of the Rhyl Urban District Council on Nov. 11th laid before the Duke of Westminster a request that the hospital should be erected on a site in the Marine Drive instead of the present site on the Promenade. In order to induce the Hospital Committee to accept the proposal the council offered £2600 and the owners of adjoining property a further sum of £800. The Duke of Westminster pointed out that the council's offer was not very liberal, and that by accepting it the committee would sustain a loss of several hundred pounds; the matter would, however, be considered.

ROYAL INSTITUTION.—The Christmas course of lectures adapted to a juvenile audience at the Royal Institution will be delivered this year by Professor John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Physiology in the University of Glasgow, and formerly Fullerian Professor of Physiology in the Royal Institution. The subject will be Sound, Hearing, and Speech, and the lectures will be experimentally illustrated. The first lecture will be delivered on Saturday, Dec. 28th, at three o'clock, and the remaining lectures on Dec. 31st, 1895, and on Jan. 2nd, 4th, 7th, and 9th, 1896.

DIPHTHERIA IN LONDON.—In London proper and the suburban districts forming the "Greater London" of the Registrar-General, there were registered last week no fewer than 103 deaths from diphtheria, and of these the county of London contributed 75, the totals for the county in preceding weeks having been respectively 76, 61, and 72. Last week the number exceeded the corrected average for the forty-fifth week of the years 1885–94 by 32 deaths, and thus manifested an increase of nearly 75 per cent. The seriousness of this continued state of things cannot be gainsaid. As usual, all but a very few of the deaths occurred in young persons between the ages of one and twenty years, and the sanitary areas furnishing the largest numbers were Islington with 7, and Kensington, St. Pancras, Chelsea, and Greenwich each with 6 deaths. The admissions were again little over 100 cases in the week, a quite disproportionate number, having regard to the amount of the disease throughout the metropolis; and the number of patients remaining under treatment on Saturday last, 683, was but slightly in advance of previous totals—namely, 675 and 671. Of the 18 deaths in the outer ring, 7 took place in persons belonging to Edmonton, and 3 in residents in Wimbledon districts. The malady is apparently affecting suburban localities on all sides of London, and we hear of it from time to time in more remote parts of the home counties.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADAMS, F. E., M.D., M Ch. Irel., D.P.H. Camb., has been appointed Medical Officer of Health for the combined Sanitary Districts, Hertford.

ANDERSON, D. A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Cuckfield Sanitary District, Teesdale Union.

ARCHER, H. R., M.D. Lond., L.R.C.P., M.R.C.S., has been reappointed Medical Officer for the No. 1 Sanitary District of the Royston Union.

BERLYN, J. A., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Surgical Officer to the Children's Hospital, Birmingham.

BEVAN, R., L.R.C.P. Lond., M.R.C.S., D.P.H., has been reappointed Medical Officer to the No. 1 Sanitary District of the Romney Marsh Rural District.

BRUCE, W. J., L.R.C.P. Lond., M.R.C.S., has been appointed First Assistant Medical Officer of the Gordon-road Workhouse and the Infirmary, Parish of St. Giles, Camberwell.

CHILD, E., M.R.C.S., has been reappointed Medical Officer of Health to Malden Urban District Council.

CLARKE, T. H. M., B. A., M.B., B.Ch., B.A.O. Dub. Univ., has been appointed Senior Resident Surgeon to Jervis-street, Hospital, Dublin.

DAIN, H. G., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Children's Hospital, Birmingham, vice Hickinbotham, resigned.

DUNCAN, ROBERT BRUCE, M.D., B.S., B.Hy. Dunelm., has been appointed Medical Officer for the Bradninch District of the Tiverton Union.

GILFILLAN, S. J., M.A., M.B. & C.M. Edin., has been appointed Second Assistant Medical Officer to the Norfolk County Asylum, Thorpe.

GOADBY, A. L., L.D.S.R.C.S., has been appointed Consulting Dentist to the Royal Berks Hospital, Reading.

HARDY, C. M., M.B., B.S. Durh., has been appointed Medical Officer of Health for the Darlington Rural Sanitary District.

HAYWARD, J. W., M.R.C.S., has been appointed Medical Officer to the Whitstable Urban District Council.

JONES, C. A., L.R.C.P. Lond., M.R.C.S., has been appointed Second Assistant Medical Officer at the Gordon-road Workhouse and the Infirmary, Parish of St. Giles, Camberwell.

KNOX, J. J., M.B., B.C. Camb., F.R.C.P. Lond., has been appointed Medical Officer to the East and West Molesey District Council.

LEES, E. LEONARD, M.D., C.M. Edin., M.R.C.S., has been appointed Physician to the Hospital for Sick Children and Women, Bristol, vice W. Barrett-Roué, resigned.

Births, Marriages, and Deaths.

BIRTHS.

ALFORD.—On Nov. 11th, at Royal-crescent, Weston-super-Mare, the widow of the late George Ernest Alford, M.R.C.S., L.R.C.P. Edin., of a son.

BORROWMAN.—On Nov. 9th, at Dunreggan, Elie, the wife of Philip G. Borrowman, M.B. Edin., of a daughter.

CARTER.—On Nov. 8th, at Gloucester-row, Weymouth, the wife of R. W. Carter, M.D., Deputy-Surgeon-General, Army (retired), of a daughter.

WARDE.—On Nov. 9th, at Knowsley, Prescot, the wife of Wilfrid Brougham Warde, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

BULLOCK—WILLETT.—On Nov. 6th, at Christ Church, Folkestone, Henry Maurice Bullock, M.R.C.S., L.R.C.P., of Heatherley, Hounslow, to Nina Maude Dacre, youngest daughter of the late Edmund Sparshall Willett, M.D.

JÄGER—DOWDING.—On Nov. 7th, at St. John's, Kingston-on-Thames, by the Rev. Arnold Letchworth, M.A., Harold J. Jäger, M.R.C.S. Eng., L.R.C.P. Lond., A.K.C., to Lucy Adelaide (Missie), only daughter of the late Rev. Chas. Dowding, Rector of Priston, Somerset, and Mrs. Dowding, of Surbiton.

JEROME—TAYLOR.—On Nov. 7th, at the Parish Church, Sutton Coldfield, by the Rector, the Rev. W. C. R. Bedford, George Percy Jerome, M.B. Lond., third son of the late J. S. Jerome, Esq., Holland House, Sutton Coldfield, to Edith Sarah, fourth daughter of S. A. Taylor, Esq., The Hollies, Four Oakes.

SIMPSON—TAYLOR.—On Nov. 6th, at the Parish Church of St. Mary, Bocking, Essex, by the Rev. Trevor Evershed, curate of Mundham, Sussex, Charles Shackleton Simpson, L.R.C.P., M.R.C.S., of 2, Portland-road, Hove, second son of Thomas Simpson, Esq., of Shipstreet, Brighton, to Lily, elder daughter of Thomas Taylor, Esq., M.R.C.S., of Bocking, and niece of the late J. H. Partridge, Esq., J.P., of Colchester.

THANE—BEATTY.—On Nov. 7th, at St. Matthias' Church, Richmond, Philip Thornton Thane, L.R.C.P. Lond., &c., of Yass, N.S.W., fourth son of Geo. D. Thane, M.D., to Pauline Willis, the fourth daughter of J. Guinness Beatty, M.D., of Grosvenor-terrace, Prince's-park, Liverpool.

DEATHS.

BISSILL.—On Nov. 7th, at Sleaford, in the 79th year of his age, John Henry Bissill, F.R.C.S.

COCK.—On Nov. 6th, at 1, Porchester Houses, W., Frederick Cock, M.D. Edin., M.R.C.P. Lond., aged 67.

FORD.—On Nov. 5th, at Cheltenham, Frederick Thomas West Ford, M.R.C.S. Eng., aged 73, for nearly thirty years Chief Medical Officer to the Police Force of Victoria, Australia.

JEFFERYS.—On Nov. 10th, at St. Augustine's-road, N.W., William Edward Jefferys, M.R.C.S., in the 71st year of his age.

KOUGH.—On Nov. 11th, at his residence, Albany-grove, Monkstown, county Dublin, Edward Kough, M.B., M.Ch. T.C.D., in his 58th year.

PRICE.—On Oct. 10th, at 136, Priory-street, Carmarthen, South Wales, of scarlet fever, Eleanor Maud, youngest daughter of R. G. Price, M.D., aged eight years.

ROSE.—On Nov. 7th, at Edgehill House, Ipswich, Caleb Rose, F.R.C.S., M.R.C.P., aged 75.

SMITH.—On Sept. 3rd, at Kamara, St. Kilda, Melbourne, Australia, Louisa Janet Smith, only sister of Surgeon Albert O. Bobardt, R.N., H.M.S. *Dart*, Australian Station.

SWETE.—On Nov. 10th, at Castle-hill, Fishguard, Pembrokeshire, Charlotte Bayley (Lillie), the loved and loving wife of Horace Lawton Swete, L.R.C.P. Lond., and daughter of the late C. Fryer Lyall, Esq., of Bath and Barbadoes.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY.—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Papers:—Mr. Edmunds: Cystic Accessory Thyroid.—Mr. Targett: Classification of Sarcomata connected with Bladder.—Mr. Marriott: Acute Tuberculosis of Spleen; Removal by Operation.—Dr. Rundle: Primary Epithelioma of Ureter.—Mr. D'Arcy Power: Diffuse Lipoma of Hand and Fingers. Card Specimens: Dr. Claremont: Extensive Ulceration of the Œsophagus.—Dr. Walsham: Meckel's Diverticulum with an Attachment to Mesentery.

WEDNESDAY.—ROYAL METEOROLOGICAL SOCIETY (25, Gt. George-st., Westminster).—7.30 P.M. Mr. John Eliot: On the Origin of the Cold Weather Storms of the year 1893 in India, and the Character of the Air Movement on the Indian Seas and the Equatorial Belt, more especially during the South-west Monsoon Period.—Mr. Charles Davison: The Diurnal Variation of Wind Velocity at Tokio, Japan. Mr. W. H. Dines will show his Experiment illustrating the Formation of the Tornado Cloud.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-sq., W.).—8 P.M. Mr. M. J. Michael: Numerical Aperture Reconsidered.—Mr. F. Chapman: Foraminifera of the Gault of Folkestone.

SOCIETY OF ARTS.—8 P.M. First Ordinary Meeting. Opening Address by Major-General Sir John Donnelly.

NORTH-WEST LONDON CLINICAL SOCIETY.—8.30 P.M. Clinical Cases.

THURSDAY.—MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11, Chandos-st., Cavendish-square).—2 P.M. Council Meeting. 4 P.M. Dr. W. Gilmore Ellis: Latah.—Dr. Morrison: Short Notes of a few cases of Epilepsy affecting Special Nerves and their Associated Mental State. 6.30 P.M. Members dine at the Café Royal.

HARVEIAN SOCIETY.—8.30 P.M. Mr. Juler: The Pathology and Treatment of some forms of Iritis.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Introductory Address by the President. Mr. Richard Lloyd: Six Hours' Administration of Chloroform in a case of Cumulative Poisoning by Hypodermic Injection of Strychnia.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—Clinical Evening. Mr. W. A. Lane: Cases of Excision of the Temporo-Maxillary Joint in Children.—Dr. Harry Campbell: A case of Premature Puberty and a case of Rheumatoid Arthritis confined to the Elbow-joints.—Dr. R. Hingston Fox: A case of Meningocele.—Mr. J. H. Morgan: Double Penis and Malformation of Genitals, Hare Lip and Cleft Palate, with Deformity of Ear and Face, and with Auricular Appendage.—Dr. Buzzard: A case of Charcot's Joint Disease.—Dr. Colman: Mother and Child with Idiopathic Muscular Atrophy.—Mr. O. Paget (introduced by Mr. S. Paget): A case of Myositis Ossificans.—Mr. H. H. Clutton: Two cases of Deficiency of Tibiæ.—Mr. C. S. Wallace: A case of Ligature of the Femoral Artery and Vein for Secondary Hæmorrhage.—Dr. F. R. Walters: A case of Myxœdema.—Mr. W. H. Battle: A Modified Incision for Removal of the Vermiform Appendix.—Mr. Makins: A case of Ligature of both External Iliac Arteries by the Transperitoneal Method.—Mr. H. Paterson: A case of Extensive Skin Grafting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. E. Woakes: Tinnitus and Vertigo.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Percy Smith: General Paralysis of the Insane.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

HOSPITAL FOR CONSUMPTION, &c. (Brompton).—Dr. C. Y. Biss: Hæmoptysis.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—5 P.M. Dr. Morgan Dockrell: Pustular Dermatitis.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Swinford Edwards: Rectal Surgery.

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-st., 3.30 P.M., Mr. Donald Gunn: Ocular Evidences of Hereditary Syphilis.—National Hospital for the Paralysed, Bloomsbury, 2 P.M., Dr. Tooth: Hemiplegia.—Central London Sick Asylum, Cleveland-st., 5.30 P.M., Mr. Bryant: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M. Prof. Crookshank: Erysipelas and Suppuration.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Percy Smith: Puerperal and Lactational Insanity.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Parasitic Diseases (Animal).

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

PUBLICITAS PUBLICITATUM, OMNIA PUBLICITAS!

WE take the following from the *Educational Times*:—

> The seats of St. Margaret's, Westminster, were thickly strewn, on the last Sunday in October, with pink leaflets to the following effect: "Tastefully printed and bound in cloth, gilt lettered, price 2s. 6d. Four Foundation Truths: a Message to Churchmen of To-day. Containing"—four essays by four M.A.'s—"with a preface by the Very Rev. ——, Dean of ——."

Is there to be no day or place of rest from the pushing hawker? asks our contemporary, whose query, we hope, may catch Canon Eyton's eye.

Mr. L. Barry.—We agree with all our correspondent says, but the grievance has so often been ventilated that we cannot suppose that any people remain in ignorance, while the actual culprits are not likely to be deterred by anything which appears in our columns or in those of any other journal.

Mr. James Dingley.—We regret that we can afford no information beyond that which may occasionally be derived from our advertisement columns.

DIURETIN KNOLL.

To the Editors of THE LANCET.

SIRS,—I shall be glad if any of your readers will give me any information with regard to the use and therapeutic and tonic actions of Diuretin Knoll. The dose is a minimum of eighty grains per diem. I ordered this dose for a patient suffering from chronic nephritis, but when she had taken forty-five grains in the manner prescribed on the bottles she became deadly faint, with partial loss of consciousness, violent palpitation of heart, and low blood-pressure. Nausea followed, and lasted with faintness and insomnia for twenty-four hours.

I am, Sirs, yours truly,

Ingatestone, Nov. 11th, 1895. E. CLOETE SMITH.

"THE KOMICAL KALENDAR."—A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a statement quoted in this week's issue of THE LANCET. I beg to deny that I ever made such a statement, and to affirm that the mention of my name in this instance, as in many others, is entirely without my knowledge or sanction.

I am, Sirs, yours faithfully,

Hill-street, Berkeley-square, W., Nov. 9th, 1895. ROSSON ROOKE.

"PROTONUCLEIN" IN CANCER.

A CORRESPONDENT asks for information respecting what he terms the "new cure for cancer"—namely, "protonuclein"—introduced by Professor Schweitzer and used by Dr. Rork Conner and Dr. Wills of New York. We think that we may safely say that this remedy has not been tried in this country, and we frankly confess that its very existence was unknown to us. We are acquainted with a paper on "Nucleins," published in the *New York Medical Record* of Sept. 28th, in which the writer (Dr. Bleyn) speaks of different preparations from ova of animals which, he says broadly, he has used "in cancers, fevers, and phthisis," but his statements are far too general to permit of much attention being paid to the subject. Of course, it may be different with the authors noted by our correspondent; but we would impress upon him the fact that the evidence must be very complete and circumstantial before the medical profession will recognise that a remedy has been found which can *cure* malignant disease. Perhaps he would kindly acquaint us with the sources of his information on "protonuclein."

M.D.—The question is not absolutely settled; nor can it be until a careful record of a large number of cases is put in evidence by persons in a position to trace out the family ramifications and to be familiar with the family taints. THE LANCET of March 13th, 1875, summed up the situation generally, while an exhaustive paper by Dr. William Robertson, which appeared in THE LANCET of Sept. 8th, 1894, dealt with the subject of deaf-mutism in this connexion. Our correspondent is also referred to an article in the current number of the *Practitioner*. It must be remembered that consanguinity in marriage raises heredity to its highest power, so that the offspring would have a double chance of inheriting a taint that might with probability be present in each parent. Deaf-mutism is believed to be the commonest defect met with in the children resulting from the marriage of cousins.

F. F. and R. H. M.—The British Medical Benevolent Fund, the Royal Medical Benevolent College, the Society for the Relief of Widows and Orphans of Medical Men, and THE LANCET Relief Fund.

"PRACTICAL DISINFECTION OF ROOMS."

To the Editors of THE LANCET.

SIRS,—I see in this week's issue of THE LANCET an Annotation on the "Practical Disinfection of Rooms" and the uselessness of relying on sulphur fumes. I venture to send you a copy of a little work I have compiled, in which, appreciating the probability that sulphur will soon have to be dethroned from its position, I have tried to pave the way for a change of opinion by giving the statements against it and showing that other means must be used, such as complete disinfection of clothes, bedding, and person, and washing of all washable surfaces with corrosive sublimate in addition, for safety.

I should like to have said more, but as I found on inquiry that so many medical officers of health and professional disinfectors pinned their faith upon sulphur, and having nothing to take its place, I was constrained to leave it for the present, hoping to find another means by the time if ever a second edition is required.

I am, Sirs, yours faithfully,

Putney, Nov. 11th, 1895. JOHN GAY.

*** Mr. Gay sends us a copy of a most useful little pamphlet of which he is the author and which the National Health Society publishes at the modest price of a penny. The book is a little compendium of practical directions for the use of disinfectants, and among those mentioned is sulphur, and the efficacy of its vapours is questioned. We hope that the second edition Mr. Gay is preparing for will soon be required.—ED. L.

"THE INTERNATIONAL MEDICINE."

THERE is a paper which appears monthly, and which is known as the *International Medicine*, its sub-titles being, "Monthly Paper, Medical and Pharmaceutical, Analytic Review." Its price is low and its paper poor; but it is the quality of its English which we desire to comment upon, having regard to its aspiration towards international character. The first article is called "Localisation of the Muscular Sense in the Skin of the Brain"; but whether by the term "skin" the *pia meter* (*sic*) is meant or the superficial layer of brain structure does not clearly appear. The finest specimen—out of many, however—of English as she should not be written is the title of an article upon a fatal case of fat-embolism, which appears as "Mortal Greasy Embolism." There may be a want of a medical organ for the international expression of professional feeling and dissemination of medical knowledge; but there can be no scientific or social need for a sheet like the *International Medicine*.

Mr. Theo. G. H. Nicholson is thanked for his interesting communication. The method he advocates has been previously recommended by Mr. Foy and others.

Mr. Thomas Taylor.—We regret to be unable to give our correspondent any precise information.

"A FEMALE MEMBER OF THE ARMY MEDICAL STAFF."

To the Editors of THE LANCET.

SIRS,—In my former letters to you on this interesting subject I refrained from telling a story which puts the question of "James Barry's" sex beyond all doubt, being under the impression, as I was, that the narrator would himself communicate it to THE LANCET. He has not, it appears, chosen to do so; but as he laid no restraint on me I shall now place his account before your readers.

I met the colonel commanding a northern sub-district at mess shortly after the publication of "A Modern Sphinx" in 1881, and taking me aside he gave me the following startling information, and which, so far as I can remember them, I will tell in his own words:—"I was quartered as a subaltern in Trinidad while Dr. Barry was serving there in the capacity of principal medical officer. One day a friend of mine, an assistant surgeon, asked me to walk with him into Port-au-Prince. 'The P.M.O.,' said he, 'is down with fever at the house of a lady friend, but has given strict injunctions to us not to visit him. Nevertheless, I feel bound to call and see how he is. Will you come with me?' On arrival my friend entered Barry's bedroom, while I remained on the verandah. In a few minutes he called me excitedly into the room, exclaiming, as he flung back the bedclothes, 'See, Barry is a woman!' At that moment the P.M.O. awoke to consciousness and gazed at us bewilderingly. But she quickly recovered presence of mind and asked us in low tones to swear solemnly not to disclose her secret so long as she lived. As a matter of fact," added the colonel, "I have never till now mentioned the subject."

I have been given to understand that the photograph mentioned in one of my former letters as being kept under lock and key in the medical officers' mess at Netley has been sent to you. You will

INSPECTOR-GENERAL JAMES BARRY.
[From a photograph kindly lent to us by the Netley Mess.]

observe the unmistakable female characteristics of Barry's features. But what struck most people who knew her as still more remarkable was the manner in which she carried her arms—with elbows *in* instead of *outward*. In conclusion, I may add that in view of the great interest revived by this correspondence I shall without delay bring out a cheap edition of my novel, "A Modern Sphinx."

I am, Sirs, yours faithfully,

Savage Club, Oct. 29th, 1895. E. ROGERS, Lieutenant-Colonel.

P.S.—The assistant surgeon referred to died quite recently. I enclose extracts of letters from General W. Chamberlayne and Colonel R. Wilson (formerly of the 3rd West India Regiment), which will, I feel sure, be an interesting supplement to the correspondence.

General Chamberlayne writes:—"The lady doctor you allude to, I suppose, is Dr. Barry. I knew him, or her, in Jamaica. I think the account published in *All the Year Round* was pretty nearly correct, as far as I remember the general history. I do not think he, or she, wore a ring. The hair was light—I think dyed—but very thin and cut close. Spectacles were not worn, but high-heeled boots were. One peculiarity was a strictly vegetable diet—no meat, or even wine or other liquor; and a dislike of medical men. A queer fondness for animals, keeping several cats and dogs very happily; rather bombastic in speech and repellent in manner, but kind and anxious to do good to those who were never likely to become intrusive, or familiar, or troublesome to her. I must retain the feminine gender, for I believe that is only too true. When I think of the anxiety, care, and trouble she must have experienced for years to keep up the assumed character, possibly first undertaken for the love of some man, and then subsequently retained perhaps for the sake of his character as well as her own, it seems surprising how she could have possessed so many good points, for I saw a great deal of her in Jamaica. I believe her manner and speech were assumed to repel inquisitive associates. It must have been a life of great misery to have been obliged to be continually acting a part so repellent to her better feelings."

Colonel Wilson writes:—"You know almost all about Miss Barry, or nearly so. I recollect that she, like most women, loved attending weddings, christenings, &c. Also, when I was fort-adjutant in Jamaica, I used frequently to meet her at dinner at General Ashmore's, and we were all much amused at the outrageous stories she used to tell, making herself out quite a lady-killer. Also at balls, or parties of any kind, she was certain to tack herself on to the finest and best-looking woman in the room. You may remember she dyed her hair red, but had not a hair on her face, and never had. You can make all you like out of what I have now told you."

I have had letters on the subject from other correspondents, but I fear to trespass further on your space.—E. R.

TREATMENT OF SPASMODIC ASTHMA.

To the Editors of THE LANCET.

SIRS,—At the meeting of the Harveian Society on the 7th of this month, had time allowed, I should have mentioned a remedy for spasmodic asthma which, I believe, does not exist in any pharmacopœia and which I should much hesitate to recommend, but which, with one patient, proved most effectual.

A lady of position, aged twenty-two, married, and possessed of ample means, consulted many of the most eminent men in England and on the Continent for her asthma. These celebrities did her but little good, consequently she lost all faith in medical men and adopted a treatment of her own, which, I was told, never failed. Her plan was to shut herself up in a small room about 9 ft. square, allowing the gas (unlighted) to escape, and in three minutes her maid, who stood sentinel outside the door, came in and fetched her out. The patient was always in a semi-dazed state, but in a few minutes became quite herself, with free and easy breathing.

As the Extra Pharmacopœia contains many useful, many useless, and not a few dangerous remedies even in skilled hands, it might be as well in the next edition to include light carburetted hydrogen and its combinations.

I am, Sirs, yours truly,

Park-terrace, Regent's-park, Nov. 11th, 1895. EDMD. WHITE.

LUPUS AND INOCULATION BY TUBERCLE BACILLI.

To the Editors of THE LANCET.

SIRS,—I should be glad of information on the precise clinical and experimental observations (with references) where lupus has been proved to be produced by inoculation of tubercle bacilli.

I am, Sirs, yours faithfully,

Nov. 12th, 1895. "WALLACE CRAIGIE."

CHARGES FOR MEDICINE.

Justitia.—The model system of charging is to charge principally for visits and advice, making such additional charges for medicine as cover their cost and the cost of their dispensing. They should not figure in medical accounts. The Medical Act says: "Every person registered shall be entitled to demand and recover in any court of law, with full costs of suit, reasonable charges for professional aid, advice, and visits, and the cost of any medicines or other medical or surgical appliances rendered or supplied by him to his patients." An account constructed as is our correspondent's rather invites the criticism of which he complains, though there is nothing very unreasonable in the charges.

During the week marked copies of the following newspapers have been received:—*Manchester Courier, Walsall Advertiser, Northern Whig, Birmingham Gazette, Bath Journal, Glasgow Herald, Irish Times, Liverpool Express, Wellington Journal, Hull News, Leicester Daily Mercury, Sussex Daily News, Sheffield Independent, Newcastle Leader, City Press, Manchester Guardian, Provincial Medical Journal, Journal of Gas Lighting, Medical Record, Brighton Gazette, Essex County Standard, Weekly Dispatch, Sanitary Record, Lymington and South Hants Chronicle, The Sun, Glasgow Daily Record, Warrington Observer, Ashbourne News, Buckingham Express, Weekly Free Press and Aberdeen Herald, Mining Journal, West Middlesex Standard, Local Government Chronicle, Reading Mercury, Liverpool Daily Post, Builder, Bristol Mercury, Times of India, Surrey Advertiser, Leeds Mercury, Architect, Clapham Observer, Yorkshire Post, Pioneer Mail, Hertfordshire Mercury, Galignani Messenger, Guy's Hospital Gazette, Yorkshire Herald, Local Government Journal, Mallon Gazette (Stirling), Saturday Observer, Border Counties Gazette, Ashton-under-Lyne Reporter, Craven Herald, Accrington Observer, Cambridge Express, Widnes Weekly News, Wellingboro' News, Liverpool Courier, &c., &c.*

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Action and Use of Some New Synthetic Remedies.

DERMATOL AND DERMATOL "TABLOIDS."

SINCE the first communication on Dermatol, appearing in No. 24 of the *Berlin. Klin. Wochenschrift*, 1891, many reports on the new remedy have been published both at home and abroad. Further investigations in various directions seem not only to have established many of the early claims made for Dermatol, but also to have indicated fresh fields of usefulness for it.

The physical characteristics of Dermatol are now well known. It is a fine yellow powder, unaltered by exposure to light and air, insoluble in ordinary re-agents, free from taste, and entirely without odour. The latter property is especially esteemed by patients on whom the employment of strong-smelling antiseptic powders like Iodoform would entail serious inconvenience. The insolubility of Dermatol prevents its absorption, and therefore it never produces any toxic action whatever. Nearly all the writers in the medical journals remark specially upon the absolute freedom of the remedy from toxic properties, even when employed in large quantities under conditions most favourable for absorption.

A further characteristic of Dermatol is the absence of irritating properties. The unpleasant symptoms that follow the use of dressings such as Iodoform, Corrosive Sublimate, &c., are never observed with Dermatol. A similar unanimity of opinion prevails with regard to the astringent action of Dermatol, and it has been shown that by the intimate admixture of Dermatol with septic nutrient material, the development of bacterial growths is arrested. Dr. Bluhm (*Therap. Monatshefte*) has tested its bactericidal power upon twelve different kinds of bacteria, comparing the results with those obtained from Iodoform, and finding the polyseptic action of Dermatol far superior to that of its repugnant predecessor.

It is more especially indicated as an absorbent, antiseptic powder for the treatment of fresh surgical wounds, slight accidental cuts, or old non-purulent wounds. When applied as a dusting powder it rapidly absorbs the secretions from wounds of these types, and forms a very hard, dense, and closely adherent crust, hence it proves extremely useful in all cases in which astringent and drying effects are desired. It has been reported valuable in crushed and lacerated non-septic wounds, burns, and scalds, and in large crural ulcers. Before the introduction of Dermatol it was impossible to close a sewn rectal or fistular wound with any degree of security. Now, this valuable chemical forms a protective crust in a short time, under which primary healing progresses. The result is not less satisfactory in operations for prolapsus, and in rectal plastic surgery.

In gynæcological practice it is attracting a great deal of attention, in view of the reports presented to the Bonn Gynæcological Congress. Remarkably satisfactory results were reported to have been obtained by its use in the treatment of laparotomy wounds, prevalent carcinomata, myomata, deep-seated tuberculous peritoneal abscess, and in infectious catarrhs of vagina, cervix, or endometrium. This report referred to, after calling attention to the superiority of Dermatol over Iodoform, concludes: "Dermatol is absolutely unirritating, powerfully antiseptic, astringent, odourless, stable, and non-hydroscopic."

In dermatological practice it is highly recommended in the form of a 10 per cent. ointment with Lanoline for eczema in children, intertrigo mammæ, and intertrigo ani. It has been tried with excellent results as a dusting powder in dysidrosis of the hands and feet, in balanitis, in operations for phimosis, and, in alternation with antiseptic and stimulating remedies, in the treatment of bubo. For burns the 10 per cent. Lanoline ointment above mentioned is highly recommended.

Dermatol has been used with excellent results in otitis media suppurativa, otitis externa, and in a large number of cases of chronic middle-ear suppuration. The secretion was quickly reduced in quantity, and "most of the cases ceased suppuration after a few insufflations." In otitis externa it was employed (*Therap. Monatshefte*, 1892, No. 12) with excellent results. After two to five applications of the powder the aural cavity was dried, the swelling reduced, and the eczema healed. When used to check a *purulent* aural discharge insufflations should be alternated with irrigations with an antiseptic solution, such as that made by dissolving a "Soloid" of Iodic-Hydrarg. in a pint of water.

In ophthalmic work it has been used in the after-treatment of operations, and Dr. Werther reports successful results with Dermatol in phlyctanular inflammation of the conjunctiva in scrofulous children. It is an advantage that Dermatol can be employed for scrofulous patients simultaneously with potassium iodide, which is contra-indicated in conjunction with calomel.

Dermatol supplied to the Medical Profession in 1 oz. tins at 1s. 2d. each. For the internal administration of Dermatol, "Tabloids" containing 4 gr. each are recommended as th most convenient form for administration, and are supplied to the medical profession in bottles of 24 and 100 at 8d. and 2s. each.

PHENOSALYL.

This is a clear, syrupy liquid, consisting of a mixture of Benzoic, Salicylic, and Carbolic Acids, melted together and dissolved in Lactic Acid. The results of all bacteriological trials with the mixture have shown that it possesses an antiseptic power considerably superior to that of carbolic acid; these trials dealt with the respective micro-organisms peculiar to the following diseases:—Cholera, Anthrax, Pneumonia (Fraenkel), Bacillus Pyocyaneus, Typhus (Eberth), Diphtheria, Tuberculosis, and with Staphylococcus Pyogenes Aureus. The results of these trials were completely satisfactory; even the last-named bacterium (which is the most resistant known) is immediately killed by a 1 per cent. solution, whilst to attain the same result with carbolic acid it is necessary to expose it to the action of a 2½ per cent. solution for at least one minute. Phenosalyl has been used by Duloroy in the sterilisation of instruments, of gauze, and of different organic substances like blood, as well as decomposing urine and the saliva of consumptives, with most encouraging results. The numerous tests to which Phenosalyl has been subjected show that, while it kills the bacteria of pus after one minute's contact, it does not irritate the skin, nor has it any corrosive action on instruments. A communication by Professor Fraenkel summarises the advantages of Phenosalyl over other antiseptics as follows: Easy solubility in water; no danger of toxic symptoms; a pleasant and non-persistent odour which does not cling about the hands or clothes. Solutions of Phenosalyl have no corrosive action on the skin, the mucous surfaces remain smooth and slippery, and do not become dried up, as is the case after washing with carbolic acid or corrosive sublimate. Supplied to the Medical Profession in 2-oz. bottles at 10d. per bottle.

The above are produced by the Farbwerke, vorm. Meister, Lucius, and Brüening, Hoechst-am-Main, and specimens may be had, as well as literature bearing on these and other new products, upon application to the agents.

Schieffelin's

(NEW YORK, U.S.A. ESTABLISHED 1794.)

PERFECT PILLS.

NEW FORMULÆ BOOK NOW READY.

BLAUD'S *(a)* { Ferri Sulph., 1½ grs. / Potass. Carb., 1½ grs. }

BLAUD'S *(b)* { Ferri Sulph., 2½ grs. / Potass. Carb., 2½ grs. }

BLAUD'S *(Modified)* { Ferri Sulph., 2½ grs. / Potass. Carb., 2½ grs. / Acidi Arseniosi, 1-40 gr. }

THE MOST RELIABLE IN THE MARKET.

These Pills have a special coating which is superior in every respect to the ordinary Gelatine, Sugar, or Pearl Coatings, being absolutely tasteless, quickly soluble, and, owing to its transparency, the natural colours of the Pill mass can be readily distinguished.

In prescribing please specify "**Schieffelin.**"

Price List of Pills and Book of about 400 useful Formulæ, including those of the British Pharmacopœia, sent free on application; also Samples if required.

An Address
ON
THE USE OF DRUGS.

Delivered before the Harlesden Medical Society on Oct. 11th, 1895,

BY W. R. GOWERS, M.D. LOND., F.R.S.,
CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, ETC.

MR. PRESIDENT AND GENTLEMEN,—I am glad to have an opportunity of exchanging some thoughts with members of the branch of the profession to which I have not the honour to belong. The chief line of cleavage which runs through the profession is that which separates the many, whose work is primarily to apply knowledge, and the few, whose work is primarily to advance knowledge, and also to bring from the front, when needed, the greater particular knowledge which less wide work has permitted them to obtain. I use the word "honour" advisedly, because I hold that of the two branches the work of the general practitioner is the more deserving of honour. His work is, perhaps, not more arduous, and perhaps, on the whole, has a more adequate practical reward, but it is destitute of the incentive which science supplies to those who serve her with pure heart and earnest endeavour, and which makes the labour, at least for such, its own reward. I have also used advisedly the word "particular" in contrast to the word "general." The accurate antithesis would be "special." But this word now involves other conceptions. I think, indeed, that those who are strong in their objection to specialism in medicine scarcely realise how inevitable it is. It begins as soon as the boundary of general practice is passed. The division of medicine from surgery is specialism. But this subject is too commonplace for me to waste your time by dwelling on it—the necessity of restriction of range of work in order to secure depth, or the mistake that is made when specialism is confounded with exclusivism. Yet I must, in passing, mention and emphasise one important fact: that the special implies the general, and that no man can be a specialist who has not an adequate practical acquaintance with the whole range of at least one of the two great branches of professional knowledge. Indeed, he must go further. I had occasion lately to point this out to a class of students when lecturing on a case of paraplegia from compression of the spinal cord in consequence of vertebral caries. Caries of bone is regarded as a purely surgical affection; whatever its effects, the treatment it needs, apart from operative procedure, is the same. Yet, as soon as the caries of the spine influences the spinal cord, the case is transferred not only to the physician but to the physician who devotes his attention chiefly to one class of diseases, those of the nervous system. A few days ago I found that a patient had been admitted into the National Hospital for the Paralysed and Epileptic, under my care, who presents an illustration of this which may be termed an *extensio ad absurdum*. He has caries of the spine, but he has no nerve symptoms, nor has he had. He was sent there apparently because his disease *might* cause paralysis. The fact is an unquestionable compliment to the Hospital, but if the practice were extensively adopted—as, for instance, in Bright's disease, heart disease, &c.—the capacity of the Hospital would have to grow and multiply exceedingly. Diseases of the nervous system, however, abound in illustrations of the degree to which the special involves the general. In the case of sudden lesions of the brain, hæmorrhage or softening, the treatment needed is only, in a small degree, treatment of the nervous system. For the most part, it is treatment of the vascular system, or of the heart, or of the general blood state; and any good that can be done is to be effected only through a knowledge of all these morbid states and of their treatment. As a matter of fact, diseases of the nervous system so called are widening out in ever-increasing degree. The extent to which symptoms apparently of purely nervous nature depend primarily upon blood states and constitutional conditions is becoming more and more apparent, and compels not only wider knowledge, but wider familiarity with such diathetic states and their indications. Some of them are only disclosed by their effect upon the nervous system. There is no part of medicine in which a nerve specialist must not be at home. I have sometimes thought that those who look widely through a narrow aperture may see more distinctly than those whose gaze ranges equally over the whole landscape. Light may hinder vision as well as aid it. But this is certain: no part of pathology is, or can be, isolated. Unless special work is based upon general and thorough knowledge it is unsafe.

It is of great importance that these facts should be recognised by practitioners. Consultants are, for the most part, that which practitioners, by their action, decide. With rare exceptions, a physician is not "run after" by the laity unless he has first received the stamp of general professional approval. Besides this indirect influence, the total amount of direct power in the hands of general practitioners is enormous. They are apt to complain of evils for which they are themselves really responsible. They too often condone in action that which they condemn in words.

It may occur to you that, in speaking of the general practitioner, I am speaking of that of which I know little. But I am not quite ignorant of general practice. It is indeed probably true that the members of the two great branches of the profession—the general practitioners and the consultants—are less able than they were formerly to understand each other, and to enter into each other's modes of thought and limitations of action. Neither has taken part in the practical life of the other in the way through which alone it can be thoroughly understood. I count myself fortunate in having entered the profession by the path which so few now tread—that of apprenticeship to a country practitioner. The changing times, the increased demands of the curriculum, and the long period of formal work, have made this method for the most part impracticable. No doubt the change is wise. The first two years are now more profitably spent. And yet I learnt much which I would not willingly forego during the period in which my professional work consisted of making up pills and bottles of medicine, sometimes rising to the dignity of assisting at an operation, of watching a child in convulsions, or of pulling out myself a tooth that was very loose. I learned something from these processes. In fact, I learnt much from the dispensing work. These things, moreover, left me time to work up, almost afresh, for the matriculation of the University of London. I also learned to love Tennyson and to worship Ruskin, while my summer afternoon rambles enabled me to do that which I have found most useful—to learn much of practical British botany. Botany stands low among the subjects of medical study. With that I have nothing to do. But of this I am certain—there is no part of science which is indirectly of so much service to the practitioner as practical British botany. The process of the identification of plants by the descriptions, the training it involves in accurate observation, in careful comparison, and in giving the proper relative weight to different features, is essentially the same as that which is needed in the diagnosis of disease. No subject affords mental training quite so effective for the practitioner's work. But my wandering path has taken me away from the lessons for which I introduced the subject of apprenticeship.

I gained two perceptions of the work of the practitioner which I have never lost. The first is the narrow limit which circumstance sets to the therapeutical scope of the average practitioner. By "average practitioner" I mean the practitioner whose work represents that of the majority, the work which lies among the lower classes or among the lower middle classes—among the poor, commonly so called, and among those middle classes to whom the present day has brought the poverty involved in augmented needs and lessened means. If the work of the practitioners of this country were measured by statistics, would not these classes make up at least four-fifths of it? Of such work is not the following statement true? With the exception of the cases of acute disease, in which the means are more varied by which the sufferer may be kept in life and conducted back to health, the therapeutical means the practitioner can employ are almost limited to the administration of drugs. Are not his means almost restricted to the method of treatment to which it is now customary to refer in terms not far removed from those of contempt? Where is the room in such practice for the many measures of which we hear so much in the present day—

Digitized by Google

measures which are developed in such elaboration of detail, and described in even a greater elaboration of terms descriptive and commendatory? These systems of treatment pass in waves of fashion across the surface of suffering humanity with well-filled pockets. The rise and fall of these must be watched from afar with feelings allied to wonder by those practitioners whose lot is cast in places less happy and whose patients belong to classes less favoured. The second fact that was impressed upon me was that this method of treatment by drugs does, in most cases, not only a definite but a great amount of good. This impression was derived from observation of the effects of the routine mixture and the routine pill, devised for those whose life led to like suffering and could be relieved by like measures. I have never lost the impression, and it has been deepened by my own subsequent observations.

The physician's experience of the use of drugs is acquired under conditions not altogether favourable. It is his task to deal with cases that have resisted the efforts of practitioners who are often wise, persevering, and equipped with knowledge in a degree increasingly adequate and effective. Success in treatment by drugs, after such antecedent efforts, seems to me to testify to the undeveloped capacities in the means employed. However this may be, I am convinced that the method of treatment to which the average practitioner is chiefly restricted now, as he was in the past, to which he is limited by a compulsion not less at the present time than in former days, has not only a power that can be realised now but also a potentiality yet to be developed.

It has, therefore, been with great interest that I have seemed of late to see more clearly why this should be. When I say "I have seemed to see it," I do not mean that it is not conspicuous to many. The scepticism regarding the use of drugs to which I have referred is, I think, less now than a few years ago. One favourite foothold was the statistical demonstration of inutility—as, for instance, that the average duration of acute rheumatism was the same whatever treatment was employed or when no agents were used. That is no longer possible, since we have sought help from the willow which casts its shadow on the damp places in which there thrive the bane and antidote. Since the salicylates were employed I fancy the significance of the loss of this convenient argument has been felt. Then, moreover, the empirical advice, "Try all things; hold fast that which is good," to which in the hands of peasants we owe many of our most precious aids, has been applied to the results of modern chemistry, and every tangible achievement of science has been seized by the "advanced pharmacy" of the present day.

But can we discern the reason why drugs are useful? Consider. I show you two tubes. Each contains a small quantity of a white powder—about half a teaspoonful. Each consists of the same elements. One is practically harmless; the other contains within it the power of death to 1000 men. The one is quinine; the other is aconitia[1]—the alkaloid which makes so deadly the plant whose flower our ancestors called "monkshood" in the far-off days when the original was always before their eyes. It is an almost startling fact that in this minute quantity of powder, hardly visible to those at a distance, there is such a potentiality of death. Picture to yourselves 1000 men. That which is in this tube would end the life of every one of them. There is a latent power within this powder beside which the lightning flash is feeble, and to which the earthquake might give place, so far as the comparison depends on lethal certainty. But the resemblance in the aspect of these two substances is not all. As I said, each consists of the same elements: each is made up of carbon, nitrogen, oxygen, and hydrogen. Each consists of the elements which compose air and water, with some carbon added — soot, if you like. Why is one almost harmless, and the other a most deadly poison? I might have chosen for the lower term of the comparison a simple food, but then the amount of nitrogen would have been less, and the resemblance in construction less close. The answer may be given, "It depends upon the chemical constitution." True, but this takes us a very little way. When we discern that the difference depends upon the way in which the atoms of the elements are arranged in molecules, and the molecules are grouped together, we are no nearer an explanation. We see a little more, however, when we realise that chemical constitution means that energy is held "latent" (as it is said) ready to be released when the elements can form simpler, closer compounds, and that on the same kind of constitution and the same kind of simpler union, and similar release of energy, in the constituents of the living tissues seems to depend all vital function. As far as we can see all the energy which is released in the animal body is released in consequence of chemical union under the mysterious influence of life. When such union and such release are going on, the process may be changed entirely by the contact of molecules of allied constitution, with latent energy on the point of release, so held as to blend with that which is being set free as living tissue. Blending with this it may augment or oppose it. Remember that a difference in chemical constitution means a difference in the readiness with which the elements separate and re-unite, and on this depends the effect exerted by the energy they bear. I have recently endeavoured to explain this in a small book,[2] in which you can, if you desire, pursue these conceptions.

Nerve force, as far as we can see, is the result of such chemical change occurring under the influence of life in the molecules which compose nerve tissue. Chemical compounds may come into relation with the substance in which the change is occurring without exerting the slightest influence upon it. But another substance may come, even in amount inconceivably minute, whose molecules are so arranged as to fit in, as it were, with the changing molecules of the living tissue. The energy the new molecules bear seems to blend with that which is in process of ordered release in the living tissue, and to blend so suddenly and so effectively as to derange it entirely. The various nerve tissues which compose the centres seem to us the same, but they must differ in their precise chemical nature and in the precise chemical action which their life-work involves. This fact is revealed to us only by their different response to different chemical agents, but the revelation is often a startling one. The difference in response is certain, the uniformity in the nature of the agent is certain, and therefore the difference in result must be due to a difference in that on which the agent acts. Although we have no other evidence of this, consider the absolute significance of such facts as that atropine acts first upon the nerve substance of the eye, and strychnia upon that of the spinal cord. Such an influence as I have spoken of seems to be almost universal in the case of aconitia. Its contact with any acting nerve structure seems to be, as it were, so direct, instant, and precise as to generate, as it were, an avalanche of energy, sweeping all before it, or opposing the process of liberation of energy with a momentum that involves a sudden stillness among the whirling atoms whose throb is far below the range of human sense. Among the nerves thus influenced may be those on which depends the action of the heart, and with a sudden spasm or a sudden stillness the heart stops and life is ended. That which so acts we call a poison. Widely different from this as is that vehicle for energy which we call a food, the difference is one of degree. Every form of food is such by taking to the tissues new energy in fresh molecules. Between the two—the poison and the food—there is an almost infinite gradation of substances whose influence is exerted in like way by chemical compounds upon the chemical processes of life, upon the state of nutrition, and upon the mode of action of the living tissues. It is in this intermediate region that there is the range of therapeutic influence conveyed by the vehicles we call drugs. The difference is of course in part one of quantity. But it is by the relation of the latent energy of the agent to the energy being released in the tissue, and to the secondary effect of the action thus produced upon nutrition, that one wide scope for the influence of drugs can be readily perceived. There are others, but they are different aspects of the same influence, and the facts may, I think, be best epitomised by the statement that treatment by drugs would be correctly named "dynamical therapeutics."

Although I believe that it is generally true that what we call "matter" is only effective, whether it be employed as food, medicine, or as poison, because it is a vehicle for energy, some apparent exceptions should be at least mentioned. In the functional action of all structures in the body, molecules are constantly passing off which, having formed with oxygen lower compounds and having

[1] For the opportunity of showing these specimens I am indebted to Mr. W. Martindale.

[2] The Dynamics of Life. London: J. & A. Churchill, 1894.

Digitized by Google

yielded their latent energy, are useless, and these are constantly being replaced by others formed under the influence of life from the material which the plasma has brought to the vicinity of the structure. It is possible that the molecules of some poisons may enter into the constitution of the tissues in abnormal amount, and thus disturb function by deranging the release of energy. There are also some cases in which atoms of some different element seem to enter and replace normal atoms, and thus derange. Whenever arsenic is brought in contact with the nerve elements, whatever be its combination, it induces not only functional but also structural changes in these, leading ultimately to their degeneration. We can only explain this by supposing that atoms of arsenic are taken up by the nerve substance in the course of the molecular renewal which attends functional action, and it is reasonable to suppose that this is due to its close relation to phosphorus, which we know is a constituent of the nerve material. It is possible that such substitution may take place in a slight degree without any injurious consequences, and even, in morbid states, with benefit. The influence on the nutritional process may be actually beneficial when this is already in some way deranged. It may promote the subsequent due assimilation of phosphorus, and make this more adequate and effective. Of course this is only a speculation. It is sometimes a help to conceive how that may be which we cannot but perceive as a fact.

These remarks have reference, of course, only to the medicinal agents which act through the blood. There is a considerable scope for thought regarding the action of agents which do not pass into the blood, which act only upon the surface, or on that portion of our real exterior which is within us, as the alimentary canal. In this region, moreover, there is some room for bringing conception to the test of experiment. Many purgatives, of course, act through the blood, but chemical processes seem to take less part in the operation of saline aperients. These act rather by "flushing out," the liquid in which the salt is dissolved being merely added to by osmosis and exciting contraction. The subject, indeed, requires more special study than it has received. The great service of salines seems to me to be effected by removing that which would be in part reabsorbed.

One other phase of modern therapeutical thought is to me a mystery. It is the contrast which is often drawn between the empirical and the rational in the use of drugs, and the disparagement of the former in comparison with the latter. Possibly it is a result of the influence of the scientific training which now dominates medical education. Beneficial as this training is, its influence may acquire a momentum that carries the effect too far, and, indeed, its influence may spread too widely for the good of those whose life is to be devoted to the hard and often routine work of applying knowledge. The intense love for pure science begotten in the better class of medical students of the present day, warm with the ardour of youth, makes them slow to sink into the grooves to which they are predestined, and hinders their perception of that which they might gain and see therein. They yield at once to the distinction between the rational in therapeutics and the merely empirical. It is all very well to esteem the rational, but we have, I hope, seen that this esteem should not be allowed to cause an aversion from that which is precious, and yet cannot be called "rational" in the common narrow sense of the word. The antithesis of the empirical and the rational is itself an error. It is an instance of a common tendency to put a positive conception into a negative word. Because the empirical is not the rational it is conceived as irrational—the only simple negative we have, but one that implies far more than simple absence of the quality excluded. The "irrational" should be merely the "not rational," but in effect it carries us as far beyond neutrality as does "unreasonable." No one means by "unreasonable" a simple absence of the quality of reasonableness. We are so accustomed to the use of the mere negative for the opposite positive that an effort may be necessary to perceive the real meaning of the words. Not only is the empirical not positively irrational: it is doubtful how we are justified in considering that a truly rational element is absent from the empirical. The term "rational therapeutics" is applied to treatment in which a drug is given with success in accordance with preconceived ideas or with a theory. The theory may turn out quite wrong, although the result is the same. What, then, becomes of the rationality? In empirical therapeutics a drug is given because it is found by experience that in the particular condition it does good. Often we cannot even guess why. But the fact remains, and surely to act upon observed experience is as truly a rational proceeding as is action upon a theory which may be incorrect. After all, the medicinal treatment which can be based upon any definite theory is small. How seldom, moreover, can we use a drug to advantage which was discovered save by the purest empiricism. In not one drug in twenty, perhaps not one in fifty, of those of most certain service, can the use be traced to anything except unguided experiment. Our knowledge of these drugs, derived from the past—and often from the distant past—must be assumed to be the result of experiments innumerable, perhaps continued through the long tens of centuries in which the human race has lived among surroundings which alike compelled and suggested endeavours to counteract disease by every available means. The need for food must itself have led men to a knowledge of the physiological action of most herbs of the field, especially when domestication brought the habits of animals under observation, habits such as must have had the power of example. It is probable that since man became able to observe and to reason, every common herb of the field and fruit of the tree has been at some time tested, and thus by slow degrees the knowledge of a physical good and evil has been acquired.

It is strange, indeed, to note how far back goes the use of the drugs on which we most rely. Most of them can be traced into the mists of the popular knowledge which it is so easy to sneer at and would be so difficult to do without, or until they are lost in the bluer mists in which the distance shrouds alike the hills of Greece and deserts of Arabia, or to the time when the world learnt its wisdom from the land where now only the sculptured symbols of man's thought stand silent in the cold moonlight of a long dead past. We smile at the popular herbal remedies. But it is to these that we owe the majority of our most useful drugs. I cannot conceive a therapeutist surveying a list of the chief drugs on which we depend in our daily work—and do not depend in vain—without a sense of wonder and perhaps of humiliation. We disinfect our rooms with burning sulphur; and so men did before the time of Homer. We purge sometimes with rhubarb, especially when some subsequent astringent influence is desirable, and so did the old Arabians for the same special reason. The value of castor oil in its chief use was familiar, probably for ages, to the natives of the East and of the West Indies before it was made known in Europe by a physician from Antigua 150 years ago. Aloes was employed in the same way long before the time of Dioscorides and Pliny. The knowledge of the influence of ergot in parturition we owe to the peasants of Germany, and the use of male-fern for tapeworm goes back to the old Greeks and Romans. The employment of mercury in syphilis by inunction and fumigation, which our nineteenth-century therapeutists regard with such satisfaction, seems to go back to the time of the Crusades, and it is said that its use can be traced in Malabar as far back as the ninth century. Podophyllum as a purgative we owe to the North American Indians. If we go through all the drugs on which we most rely we find the same story. Even in the case of those which are the latest additions to our resources, we find that, with very few exceptions, their use arose from what we must regard as pure empiricism. It was by accident that the local anæsthetic influence of cocaine was discovered. The unexpected results of simple experiment afforded us the chief use of antipyrin; and that which is perhaps the greatest practical discovery of modern times in the influence of drugs on disease—the use of bromides in epilepsy—was the result of a chance observation of its use on an allied state—also empirical. To this day we are without any rational perception of its mode of action or of the reasons for its use in given cases. I yield to no one in my sense of the importance of the rational in therapeutics; but we need to be careful lest, in contrasting the rational and the empirical, we allow our esteem for the one to induce a depreciation of the other. We can afford to despise no source or kind of help, or to permit our estimate to be lessened by the many warping influences to which our thought is liable.

I have, indeed, tried to frame a definition of rational therapeutics which I could illustrate by examples. I will not say that I have wholly failed, but my success is not sufficient to let me submit it for your consideration. But the attempt has impressed me with a doubt as to the propriety of considering that a theory, to explain an empirical discovery, makes the therapeutics rational. It is very easy to frame a theory of the action of a drug, and it is

Digitized by Google

easy to extend this theory to the nature of the disease in which the drug does good, and at the same time to ignore the many other possible ways in which the effect may be produced, and so to build from a small and uncertain foundation an edifice which some new knowledge may reduce to that which most builders call "rubbish." When I recommend a drug I am often asked, "How does it act?" Occasionally I can give some inadequate reason, but I am generally compelled to answer, "I do not know; it is often useful in this condition." Sometimes I can add, "There are several ways in which it may act." Sometimes I am obliged to say, "I have no idea how it does good." It has not been my privilege to add much to our therapeutical resources, but the few agents I have recommended have been based on pure empiricism. A few days ago I received a pamphlet from a distinguished French physician, Dr. Féré, who confirms the statement which I made sixteen years ago regarding the occasional service of borax in epilepsy, a confirmation which many others have furnished. In inveterate cases which do not yield to bromide, borax sometimes does good that is definite and distinctly greater than that which bromide produces in those cases. But I cannot say why. It was one of many things I tried, simply as a peasant might try in succession a number of herbs. Further, the diminution in the tendency to the distressing pains in locomotor ataxy which is caused by the regular administration of chloride of aluminium is so distinct that I have little doubt that the time will come when this drug will find a place in the Pharmacopœia. But I had no better reason for trying it than the fact that arsenic is a metal and so is aluminium. Of the rational we have here no trace, although I should take objection to the difference involved in the application of the epithet "irrational."

There is much more I should like to say for which time fails. I must content myself with expressing the hope that you will *use* this address. By this I mean that you will utilise it, even though the process involves tearing it to shreds. I should much like you to discuss the statement from which I started—the relation of the use of drugs to the work of the general practitioner. But I should also like you to go further—to endeavour to answer the problems that underlie my statement. I feel sure that such a society as yours cannot do more for its members, and cannot in any way do more for the profession outside, or for yourselves, than by carefully considering what drugs are found, by the personal experience of each one, to be of real use, by combining the results of personal observation, and by endeavouring in the future to organise mutual help in respect to the new therapeutic agents which the earnestness and energy of others, disinterested or interested, bestow upon us. I count it a high privilege to teach, but a privilege far higher to help men to teach themselves. It is easy to lose that which is merely received. That which is acquired is persistent. Knowledge personally gained becomes part of a man's mental self—not only as knowledge, but as power. It rises in its influence into every branch of the complex activity of practical life, and it becomes effective through its indirect effect even where we cannot trace its presence.

[*Note.*—I am glad to learn, from a letter in THE LANCET of last week, that the above suggestion is bearing fruit. I think that local medical societies would benefit by such discussions. It would be especially useful to take some related drugs, such as the antipyrine group, or the gentler hypnotics, and arrange, at a preliminary discussion, points for observation, the results to be compared and considered on another occasion a few months afterwards. Observations under these conditions would have a special value. Even in a small society—far more in a number of societies—it would be interesting to know the deliberate voting on the drugs of the Pharmacopœia that are believed, from personal experience, to be of definite value.]

CHICHESTER INFIRMARY.—The annual meeting of the governors of Chichester Infirmary was held on Nov. 14th, the Mayor presiding. The report showed that the income of the institution is insufficient to meet the expenditure, and the trustees have been requested to sell out £400 Consols. A legacy of £500, bequeathed by the late Miss Wetherstonhaugh, will be paid over before long, but an increase of at least £200 in the permanent income is required.

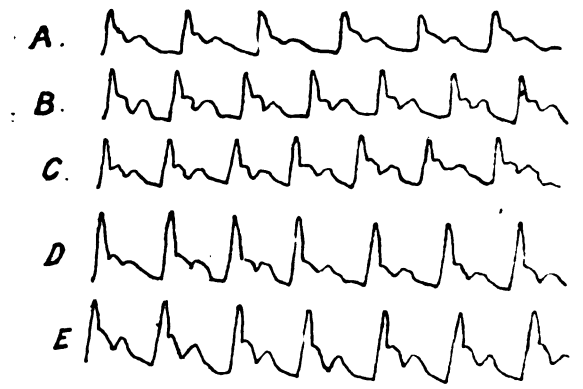
THE PHARMACOLOGY OF THE IPECACUANHA ALKALOIDS.[1]

BY ROBERT B. WILD, M.D. LOND., M.SC. VICT.,
ASSISTANT LECTURER ON MATERIA MEDICA AND THERAPEUTICS AT OWENS COLLEGE, AND LECTURER AT THE VICTORIA UNIVERSITY, MANCHESTER.

THE active principle of the ipecacuanha root "emetine" has been known to chemists since the early part of the present century, and its physiological action has been investigated by Magendie and many subsequent observers. The experimental results have in some cases been discrepant and at times even contradictory, so that doubt still exists as to the precise nature of the so-called "emetine" and its action upon the tissues. Considerable light has recently been thrown upon the cause of these discrepancies by the researches of Paul and Cownley,[2] who have shown that the ipecacuanha root contains at least two distinct alkaloids and that these exist in variable relative proportions in different varieties of the plant. They have also shown that the so-called "emetine" previously obtained by different chemists was not always the same substance, that obtained by Glenard[3] consisted of one of the two alkaloids, while other methods yielded variable mixtures. Paul and Cownley have succeeded in separating two bases, the one soluble and the other insoluble in caustic alkalies, and have named them cephæline and emetine respectively; the latter is identical with the emetine of Glenard. These alkaloids have been prepared in a pure state, carefully analysed, and their salts studied. They possess a definite composition agreeing with the formulæ $C_{14}H_{20}NO_2$ for cephæline, and $C_{15}H_{22}NO_2$ for emetine; the latter alkaloid is thus the methyl compound of the former, the chemical relation between them being similar to that existing between morphine and codeine or between caffeine and theobromine. It is important to determine whether both of these alkaloids are active principles, and if so whether their action is the same or different in kind or in degree.

The following experimental investigation of the comparative action of cephæline and emetine upon certain tissues and organs was carried out in the pharmacological laboratory of the Owens College. It is by no means exhaustive, but it affords some information as to their relative activity and gives some indications of their probable therapeutic value. It also affords another example of the effect of introducing a methyl group into a physiologically active compound, and may therefore add something to our increasing knowledge of the relation of chemical constitution to physiological action. In all cases the hydrochlorides of the alkaloids were used for experimental purposes, and I have to thank Mr. Paul for kindly placing a sufficient quantity at my disposal. I desire, also, to express my indebtedness to Professor Leech, and to Mr. J. N. Platt who has taken many of my tracings.

CEPHÆLINE HYDROCHLORIDE.



General action.—Various doses of the drug were taken by myself and two volunteers, to whom my sincere thanks are due. In some cases the drug was taken on an empty stomach, in others after meals; in the latter case the previous meal was of the same character in experiments with the two alkaloids, and the drugs were administered after the same interval of time. The effect of 5 milligrammes (about one-twelfth of a grain) taken by myself was to produce nausea, giddiness, salivation, and slight retching, but no actual vomiting. The onset of the first symptom was about twenty minutes after a dose taken on an empty stomach, and nearly an hour when the stomach contained food. The effect was also greater in the former case. Pulse tracings showed a fall in arterial tension, which reached its lowest point about an hour after the administration, and the pulse had almost regained its normal character in two hours. The duration of the nausea varied from an hour to four hours. A dose of 10 milligrammes (about one-sixth of a grain) produced slight nausea in twenty-five minutes; this rapidly increased, with retching, giddiness, salivation, and an intense feeling of illness, until vomiting occurred about an hour after the administration. The nausea and other symptoms then

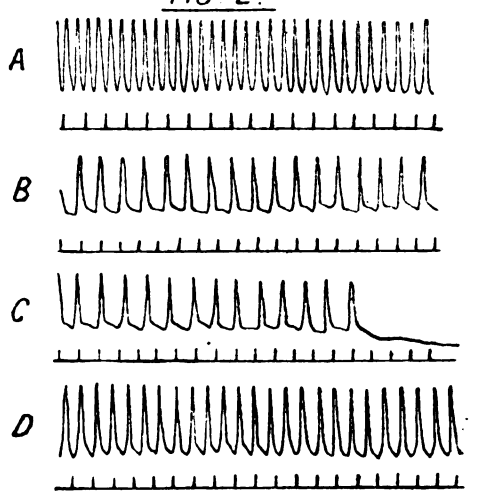
Digitized by Google

improved, but returned half an hour later for a short time; in two hours after the administration there was no feeling of illness. Pulse tracings showed a slight fall of pressure, which preceded the actual vomiting. In other persons 5 milligrammes (one-twelfth of a grain) caused either a

FIG. 1.

Pulse tracings taken by a Dudgeon's sphygmograph. A, Normal pulse before taking the drug. B, 55 minutes after cephaline hydrochloride 10 mg. (⅙ gr.), and before vomiting; much nausea. C, 63 minutes after cepaæline hydrochloride 10 mg., and after vomiting. D, 77 minutes after cephæline hydrochloride 10 mg. E, 110 minutes after cephæline hydrochloride 10 mg.

similar effect to that observed in myself or else the severe vomiting, which in my own case only occurred after a larger dose.



From the results of a number of experiments the chief points to be noted were: 1. The variations in the dose required by different individuals to produce vomiting; five milligrammes in one person produced an effect as severe as that obtained from ten milligrammes in another person. 2. The slow action of the alkaloid. In no case did vomiting occur within forty-five minutes after the drug had been taken. Larger doses would, perhaps, act more quickly, but the effect of ten milligrammes (one-sixth of a grain) was sufficiently violent to deter one from increasing the dose. 3. The secondary onset of nausea, and sometimes actual vomiting, which appeared after the first attack had passed off, in one case after an interval of two hours. It is not unlikely that this may be due to an excretion of the drug into the alimentary canal and reabsorption. Further experiments are requisite to determine this point. 4. The very marked salivation which preceded the vomiting, and which also occurred when vomiting was not produced. 5. The depressing effect upon the pulse. This was in some cases more marked after a small dose when vomiting did not occur than after a larger emetic dose. 6. Occasionally increased intestinal peristalsis was noticed, followed by a loose motion. 7. There was no noticeable effect upon the nasal mucous membrane, upon the skin, or upon the secretion of urine. The experiments did not give any information as to whether the drug acted upon the liver, save the fact that no excess of bile was present in the vomited matter.

On voluntary muscle.—The experiments were conducted by immersing the gastrocnemius muscle of a frog in a saline solution and stimulating it at regular intervals. The apparatus used was that previously described by me in a paper upon the Action of Quinine on Contractile Tissues.[4] The muscle was connected with a lever writing upon a smoked drum, the latter being either stationary during the contraction or rapidly revolving, according as it was desired to study the effect of the drug upon the vitality and power of the muscle or its effect upon the individual contractions. Cephæline hydrochloride in saline solutions containing 1 in 1000 of the drug acted as a moderately powerful muscle poison, and caused death of the tissue in from one to two hours. There was slight initial rise in the height of contraction, probably due to irritation of the motor nerve endings. There was no alteration in the shape of the muscle curve. The duration of the latent period was not affected until the muscle began to lose its vitality. Solutions containing a smaller amount of the drug produced less marked effects of the same character.

On the walls of the bloodvessels.—Pithed frogs and decapitated water tortoises were experimented upon. A cannula was inserted into one of the systemic aortæ, the other aortic trunks were ligatured, and the heart having been removed the outflow from the divided venous trunks was collected and measured at regular intervals. Saline solution (0·75 NaCl) was circulated at a constant pressure, and when the rate of flow had become fairly regular a similar solution containing the drug was substituted for a certain period of time, and then replaced by the unpoisoned saline. It was found that 1 in 5000 of cephæline hydrochloride produced a moderate contraction of the vessel walls, as shown by the diminished rate of flow. Return to or near the normal was easily effected when the poison was washed out with the pure saline, and the experiment could be repeated several times before the tissues lost their vitality. Solutions containing 1 in 10,000 and 1 in 20,000 had no contracting effect; in one experiment a slight dilatation occurred, but it could not be again obtained, and was probably not due to the action of the drug.

On the isolated frog's heart.—The heart of a frog was prepared in the usual manner with the cannula of a Williams' heart apparatus in the ventricle, and arranged to be fed with a saline solution (Professor Ringer's formula), while the beats were recorded on a slowly revolving drum. When pure Ringer's solution was replaced by one containing 1 in 20,000 of cephæline hydrochloride there was no immediate effect; a gradual slowing and diminution in the height of the individual beats was observed, and the heart stopped beating suddenly forty-six minutes after the perfusion of the poison was commenced. The pure Ringer's solution was then allowed to run through the heart in order to wash out the poison, and after four minutes it recommenced to beat, regularly and almost as powerfully as at first, but rather more slowly. After

FIG. 2.

Isolated frog's heart. Cephæline hydrochloride 1 in 20,000. Williams' apparatus. A, Beat with normal Ringer's solution. B, 35 minutes after cephæline hydrochloride 1 in 20,000. C, 46 minutes after cephæline hydrochloride 1 in 20,000; sudden stop in diastole. about forty minutes the experiment was repeated with a similar result as regards the slowing and loss of power; the rhythm then became irregular, and the heart stopped after twenty-two minutes' perfusion of the poison. There was no recovery after the second arrest. Similar experiments with a solution containing 1 in 10,000 of cephæline hydrochloride presented the same phenomena, but more rapidly induced and more marked in degree; the rhythm became irregular, and diastolic arrest occurred twenty minutes after the administration of the poison. Recovery was effected after twenty minutes' washing out with the pure Ringer's solution, and the beats were powerful, somewhat irregular, and double beats were present for about ten minutes. No more of the poison was given, but the contractions gradually

[4] Brit. Med. Jour., vol. ii. 1887.

Digitized by Google

became more feeble, and the heart died in a diastolic condition sixty-five minutes after the first administration of the drug.

On the blood pressure.—In order to test the action of cephæline upon the blood pressure a cat was anæsthetised by chloroform, tracheotomy performed, and a tube inserted connected with an apparatus for administering ether continuously during the whole of the experiment. A glass cannula was inserted into the right carotid artery and connected in the usual manner with a Ludwig's kymograph writing upon a slowly revolving drum. Cephæline hydrochloride, 20 milligrammes (one-third of a grain), was administered by hypodermic injection, a slight fall of blood pressure (two to three millimetres of mercury) occurred after a few minutes, and the new level was maintained until a further dose of 10 milligrammes (one-sixth of a grain) was again followed by a fall of two to three millimetres, the latter fall being recovered from after fifteen minutes. The rhythm and rate of the heart were not affected by the drug and the animal lived for over two hours after the administration of the poison, and was finally killed while still under anæsthesia. No vomiting or attempts at vomiting were made, and it appeared that under complete anæsthesia the drug had hardly any effect upon the vomiting centre, the vasomotor centre, or the heart, in the doses administered.

EMETINE HYDROCHLORIDE.

General action.—A dose of 5 milligrammes (about one-twelfth of a grain) produced either no appreciable effect or after the lapse of half an hour slight nausea, giddiness, and salivation; pulse tracings showed lowering of tension during the period of nausea, and in one hour and a half recovery was complete. Doses of 10 milligrammes (one-sixth of a grain) produced similar but more marked effects with retching, but, in myself, no actual vomiting. With a dose of 15 milligrammes (one-quarter of a grain) giddiness, nausea, and retching came on in twenty-five minutes, rapidly increased, accompanied by great salivation and watery secretion from the nasal mucous membrane; in forty-seven minutes vomiting occurred and again a few minutes later. The nausea improved after the vomiting, but the feeling of illness and exhaustion continued, and remained some time after the nausea had entirely disappeared, some two hours from the administration of the drug. The pulse tracings showed marked lowering of the arterial tension, and this was at its maximum some time before vomiting occurred; it was partially recovered from before vomiting, but remained below the normal for some hours.

FIG. 3.

A, Normal pulse before taking the drug. B, 15 minutes after emetine hydrochloride 15 mg. (¼ gr.). C, 34 minutes after emetine hydrochloride 15 mg., much nausea, before vomiting. D, 42 minutes after emetine hydrochloride 15 mg., before vomiting. E, 50 minutes after emetine hydrochloride 15 mg., after vomiting.

About two hours after the administration a distinct increase of intestinal peristalsis was noted, with borborygmi and a desire to empty the bowels; this culminated in a loose motion. There was no noticeable effect upon the skin or upon the secretion of urine, nor did the vomited matter contain excess of bile.

On voluntary muscle.—Emetine was less poisonous to muscle than cephæline; a solution containing 1 in 1000 of the hydrochloride was fatal in about three hours. The shape of the curve was unaltered, and the irritation of the nerve endings was much less than with cephæline; contracture was scarcely present.

On the walls of the bloodvessels.—Emetine was more powerful as a vessel contractor than cephæline; 1 in 20,000 caused well-marked contraction; also 1 in 10,000 and 1 in 5000; after the stronger solution recovery was less complete than after cephæline in the same strength. Emetine, like cephæline, acted equally well, whether the spinal cord was intact or destroyed.

On the isolated frog's heart.—The effect of emetine was very similar to that of cephæline, both in kind and degree; the variations which occurred in different experiments were not greater than are usually found in a series of heart experiments when a number of frogs are used of varying vitality and power.

On blood pressure.—The effect of emetine hydrochloride upon the blood pressure of the anæsthetised cat was the same as that of cephæline—viz., a slight lowering after subcutaneous injection in doses of 10 milligrammes (one-sixth of a grain). No attempt at vomiting was made and the beat of the heart was unaffected. In one experiment 20 milligrammes (one-third of a grain) injected into the jugular vein produced death by failure of the heart in forty-five seconds.

SUMMARY.

Both cephæline and emetine possessed a powerful emetic action; the emetic dose of the latter was, however, about double that of the former. In non-emetic doses the degree of nausea produced by cephæline was also about double that produced by emetine—e.g., the intensity and duration of the nausea following 5 milligrammes of cephæline was much the same as that following 10 milligrammes of emetine. Both alkaloids lowered the arterial tension, and little difference was apparent in small doses, but the depression produced by the emetic dose of cephæline was less than that produced by the larger emetic dose of emetine; cephæline appeared, therefore, to be distinctly preferable where a non-depressing emetic was desired. Both alkaloids caused contraction of the bloodvessels after destruction of the brain and spinal cord, but emetine was distinctly more active than cephæline: 1 in 10,000 of the latter produced little if any effect, while 1 in 20,000 of emetine was followed by marked contraction. On the heart no appreciable difference could be made out, both produced slowing, weakening, and diastolic arrest of the isolated organ; recovery was easily effected when the poison was removed. It is doubtful whether the drugs in the doses administered to men would affect the heart directly; but the fact that 1 in 20,000 caused diastolic arrest in forty-six minutes renders caution necessary in giving larger doses of the alkaloids. Both acted as muscle poisons, but cephæline had the greater toxic power, and also caused irritation of the motor nerve endings and contracture. On the secretions, salivation was well marked wherever there was nausea. Emetine caused a flow of watery mucus from the nasal mucous membrane when a full dose was given; this was not noticed after cephæline. It is possible that the expectorant action of ipecacuanha is due to a similar action of emetine upon the other portions of the respiratory mucous membrane. Intestinal peristalsis and a loose motion at times followed the administration of either alkaloid; there was never any marked purgation. No effect was noticed upon the secretion of the skin or upon the amount of urine.

Assuming the view that emetine is methylcephæline to be correct, it would seem that the chief effect of the addition of the CH_2 group was to markedly reduce the action of the compound upon the convulsive or vomiting centre in the medulla oblongata, and also to diminish the irritating effect upon motor nerve endings. The methyl compound had, on the other hand, a more powerful action as a local vaso-constrictor. The addition of the methyl group did not appear to affect the other actions of the alkaloid. With regard to therapeutic use, only accumulated clinical experience can determine their relative positions. It seems probable that in cephæline we have a powerful and certain emetic, singularly free from depressing effects when given in doses of from [illegible] to ten milligrammes (from one-twelfth to one [illegible]); its action, however, is too slow to prove [illegible] of poisoning, but in all other [illegible] it appears well worthy of trial. [illegible] conditions, as an expectorant [illegible] of

Digitized by Google

ipecacuanha where vomiting is not desired, emetine in small doses seems likely to prove of considerable value, and also as an emetic in larger doses of from ten to twenty milligrammes (from one-sixth to one-third of a grain) when a more depressing action is required. The powerful local constricting effect upon bloodvessels may also prove useful in hyperæmic and inflammatory conditions.

The wide variations in the activity of the pharmacopœal preparations of ipecacuanha may not unlikely be due to variations in the quantities and relative proportions of the alkaloids which they contain, and the use of the pure alkaloids may render one of our most valuable remedies of still greater service.

Manchester.

CONSIDERATIONS IN RESPECT TO "RETURN" CASES OF SCARLET FEVER.[1]

BY T. W. THOMPSON, L.R.C.P. EDIN., M.R.C.S. ENG.,
INSPECTOR, LOCAL GOVERNMENT BOARD.

[AS is known to our readers, we never use the term "scarlatina," but always "scarlet fever." In the MSS. "scarlatina" was used throughout, it being the official habit of the Local Government Board to employ that term and not "scarlet fever."—ED.L.]

THE subject of this paper is that of so-called "Return" Cases of Scarlet Fever, by which I understand fresh cases of the fever occurring in previously invaded households under circumstances which lead to their being attributed to the return thither of recently discharged patients from isolation hospitals. The circumstances attending the so-called "return case" appear to be somewhat as follows. A household becomes newly invaded by scarlet fever, and the person first attacked is removed to hospital. During the eight or so weeks of his detention there the household frequently, though not invariably, remains free from further invasion by the disease. A few days after his return home, however, a fresh case—the so-called "return" case—occurs, and is regarded as being due to the arrival in the dwelling of this patient from hospital. In a certain proportion of instances, though by no means in all, the recently returned hospital patient is now found, upon examination, to exhibit some evidence of desquamation, or to be suffering from discharge from the nose or ears — a discovery which is naturally held to strengthen the belief in his having reintroduced infection into the household. Such, then, is a brief outline of the history of the ordinary "return" case. Theoretically, no doubt, the subject should be dealt with upon a wider basis, since it constitutes a branch of the more general subject of the dissemination of infectious diseases by discharged hospital patients. For not only do "return" cases probably occur in connexion with other diseases—at all events, it would so seem, in connexion with diphtheria—but it sometimes doubtless happens that discharged hospital patients initiate disease in households other than their own, and that they are also the means, perhaps, of introducing disease into schools and kindred institutions. Practically, however, it will perhaps now suffice to consider "return" cases of scarlet fever, for while on the one hand it is in connexion with this disease that most experience exists in regard to cases of the sort in question, on the other hand the subject, even as thus limited, will, I think, afford as many etiological problems as may be profitably referred to within the limits of this paper.

The subject of "return cases" of scarlet fever appears to be daily attracting increased attention, both among those engaged in public health administration and also among those responsible for the administration of isolation hospitals. That it is one of some importance will, I anticipate, be generally conceded, for if it is true that the return home of patients from isolation hospitals results in any appreciable number of instances in the reintroduction of scarlet fever to their households, to that extent, it would seem, are we at present failing to obtain what, on theoretical grounds, is to be regarded as the full benefit of isolation procedures. It is clearly of importance, then, that we should endeavour to ascertain the extent of our failure in this respect, and, if possible, the means by which it may be remedied. In regard to my treatment of the subject, however, I am not prepared to bring forward the results of anything approaching to an exhaustive statistical or other study of the matter. My purpose, indeed, is rather to seek information than to give it. Having upon one or two occasions been brought into official relations with the subject, I have become impressed with the need for its more systematic study, and it seemed to me that the mutual deliberations of those interested in the matter would form a valuable preliminary to such study—in the sense, at least, of tending to clear the ground and of thus leading, perhaps, to some approach to agreement as to the general aspect from which so-called "return" cases should for the most part be regarded; and this appeared to me the more desirable in view of the diverse mental attitudes from which the subject has hitherto often been approached. Lastly, it seemed to me that of all societies the Epidemiological Society should be especially fitted to throw light upon the matter, comprising as it does among its members not only many medical officers of health, some of whom must have been brought into contact with "return" cases of scarlet fever in their public health aspect, but also not a few medical superintendents of isolation hospitals who have had experience—and doubtless anxious experience—of such cases from the hospital standpoint; while the society also of course numbers many members who, having paid special attention to general etiological questions, might be expected to throw light upon some of the more obscure problems which, as I venture to think, are not improbably involved in the subject under consideration. So far as I am concerned, therefore, my main purpose is to endeavour to set out, as a basis for discussion, the several considerations which have occurred to me as being probably bound up with this matter, and to indicate, by the way, the particular points which have appeared to me as being especially deserving of attention.

I have spoken of the subject of "return" cases of scarlet fever as daily attracting increased attention, and that such is the fact is, I think, sufficiently evident from the comparative frequency with which communications respecting it have recently appeared in the medical journals and in the annual reports of medical officers of health. I do not infer from this fact that the hospital isolation of cases of scarlet fever was in earlier years unattended by mishaps of the kind, and, indeed, it appears certain, from such inquiries as I have been able to make, that such was not the case. Nor does it seem likely that any general increase has of late years occurred in the proportion of cases of a kind that might be regarded as "return" cases to the number of patients isolated. It may, therefore, I think, be surmised that the increased attention which the matter is now attracting is due partly to the absolute increase in the number of such cases consequent upon the general growth of isolation procedures and partly to the closer scrutiny into the origin of new cases of scarlet fever which has resulted from more complete sanitary organisation, and which has been especially facilitated by the compulsory notification of infectious diseases, the result being that not only are "return" cases now absolutely more numerous, but that such as do occur are more likely to be brought to light. With respect to the growth of hospital isolation as a method of dealing with scarlet fever, it appears, from a return made to the Local Government Board in the year 1879, that only some 18 per cent. of the sanitary authorities in England and Wales had at that time made isolation provision of any sort, and I learn from Dr. Thorne Thorne's report upon the "Use and Influence of Hospitals for Infectious Diseases" that the provision made even by such authorities amounted in many instances to provision only in name. According to a further return made to the Board in 1893 it appears, however, that the proportion of the total sanitary authorities then in possession of isolation accommodation of one or another kind was practically double that of 1879. During recent years, moreover, considerable improvement has taken place in the character as well as in the amount of isolation accommodation available, and it is certain that this has largely contributed to the increased use of isolation hospitals by the public. As a general result, then, of the increase in the number of isolation hospitals, and of the improvement in their character, a considerably larger proportion of the total cases of infectious disease occurring in the country are now removed to hospital than was formerly the case; and that this is especially true in regard to scarlet fever is, I think, evident from the fact

[1] A paper read before the Epidemiological Society on Friday, Nov. 15th, 1895.

became more feeble, and the heart died in a diastolic condition sixty-five minutes after the first administration of the drug.

On the blood pressure.—In order to test the action of cephæline upon the blood pressure a cat was anæsthetised by chloroform, tracheotomy performed, and a tube inserted connected with an apparatus for administering ether continuously during the whole of the experiment. A glass cannula was inserted into the right carotid artery and connected in the usual manner with a Ludwig's kymograph writing upon a slowly revolving drum. Cephæline hydrochloride, 20 milligrammes (one-third of a grain), was administered by hypodermic injection, a slight fall of blood pressure (two to three millimetres of mercury) occurred after a few minutes, and the new level was maintained until a further dose of 10 milligrammes (one-sixth of a grain) was again followed by a fall of two to three millimetres, the latter fall being recovered from after fifteen minutes. The rhythm and rate of the heart were not affected by the drug and the animal lived for over two hours after the administration of the poison, and was finally killed while still under anæsthesia. No vomiting or attempts at vomiting were made, and it appeared that under complete anæsthesia the drug had hardly any effect upon the vomiting centre, the vasomotor centre, or the heart, in the doses administered.

EMETINE HYDROCHLORIDE.

General action.—A dose of 5 milligrammes (about one-twelfth of a grain) produced either no appreciable effect or after the lapse of half an hour slight nausea, giddiness, and salivation; pulse tracings showed lowering of tension during the period of nausea, and in one hour and a half recovery was complete. Doses of 10 milligrammes (one-sixth of a grain) produced similar but more marked effects with retching, but, in myself, no actual vomiting. With a dose of 15 milligrammes (one-quarter of a grain) giddiness, nausea, and retching came on in twenty-five minutes, rapidly increased, accompanied by great salivation and watery secretion from the nasal mucous membrane; in forty-seven minutes vomiting occurred and again a few minutes later. The nausea improved after the vomiting, but the feeling of illness and exhaustion continued, and remained some time after the nausea had entirely disappeared, some two hours from the administration of the drug. The pulse tracings showed marked lowering of the arterial tension, and this was at its maximum some time before vomiting occurred; it was partially recovered from before vomiting, but remained below the normal for some hours.

FIG. 3.

D, 42 minutes after emetine hydrochloride 15 mg., before vomiting. E, 50 minutes after emetine hydrochloride 15 mg., after vomiting.

About two hours after the administration a distinct increase of intestinal peristalsis was noted, with borborygmi and a desire to empty the bowels; this culminated in a loose motion. There was no noticeable effect upon the skin or upon the secretion of urine, nor did the vomited matter contain excess of bile.

On voluntary muscle.—Emetine was less poisonous to muscle than cephæline; a solution containing 1 in 1000 of the hydrochloride was fatal in about three hours. The slope of the curve was unaltered, and the irritation of the nerve endings was much less than with cephæline; contracture was scarcely present.

On the walls of the bloodvessels.—Emetine was more powerful as a vessel contractor than cephæline; 1 in 20,000 caused well-marked contraction; also 1 in 10,000 and 1 in 5000; after the stronger solution recovery was less complete than after cephæline in the same strength. Emetine, like cephæline, acted equally well, whether the spinal cord was intact or destroyed.

On the isolated frog's heart.—The effect of emetine was very similar to that of cephæline both in kind and degree, the variations which occurred in different experiments were not greater than are usually found in a series of heart experiments when a number of frogs are used of varying vitality and power.

On blood pressure.—The effect of emetine hydrochloride upon the blood pressure of the anæsthetised cat was the same as that of cephæline—viz., a slight lowering after subcutaneous injection in doses of 10 milligrammes (one-sixth of a grain). No attempt at vomiting was made and the beat of the heart was unaffected. In one experiment 20 milligrammes (one-third of a grain) injected into the jugular vein produced death by failure of the heart in forty-five seconds.

SUMMARY.

Both cephæline and emetine possessed a powerful emetic action; the emetic dose of the latter was, however, about double that of the former. In non-emetic doses the degree of nausea produced by cephæline was also about double that produced by emetine—e.g., the intensity and duration of the nausea following 5 milligrammes of cephæline was much the same as that following 10 milligrammes of emetine. Both alkaloids lowered the arterial tension, and little difference was apparent in small doses, but the depression produced by the emetic dose of cephæline was less than that produced by the larger emetic dose of emetine; cephæline appeared, therefore, to be distinctly preferable where a non-depressing emetic was desired. Both alkaloids caused contraction of the bloodvessels after destruction of the brain and spinal cord, but emetine was distinctly more active than cephæline: 1 in 10,000 of the latter produced little if any effect, while 1 in 20,000 of emetine was followed by marked contraction. On the heart no appreciable difference could be made out, both produced slowing, weakening, and diastolic arrest of the isolated organ; recovery was easily effected when the poison was removed. It is doubtful whether the drugs in the doses administered to men would affect the heart directly; but the fact that 1 in 20,000 caused diastolic arrest in forty-six minutes renders caution necessary in giving larger doses of the alkaloids. Both acted as muscle poisons, but cephæline had the greater toxic power, and also caused irritation of the motor nerve endings and contracture. On the secretions, salivation was well marked wherever there was nausea. Emetine caused a flow of watery mucus from the nasal mucous membrane when a full dose was given; this was not noticed after cephæline. It is possible that the expectorant action of ipecacuanha is due to a similar action of emetine upon the other portions of the respiratory mucous membrane. Intestinal peristalsis and a loose motion at times followed the administration of either alkaloid; there was never any marked purgation. No effect was noticed upon the secretion of the skin or upon the amount of urine.

Assuming the view that emetine is methylcephæline to be correct, it would seem that the chief effect of the addition of the CH_2 group was to markedly reduce the action of the compound upon the convulsive or vomiting centre in the medulla oblongata, and also to diminish the irritating effect upon motor nerve endings. The methyl compound had, on the other hand, a more powerful action as a local vaso-constrictor. The addition of the methyl group did not appear to affect the other actions of the alkaloid. With regard to therapeutic use, only accumulated clinical experience can determine their relative positions. It seems probable that in cephæline we have a powerful and certain emetic, singularly free from depressing effects when given in doses of from five to ten milligrammes (from one-twelfth to one-sixth of a grain); its action, however, is too slow to prove of much service in cases of poisoning, but in all other cases where emesis is desired it appears well worthy of trial. In acute catarrhal and febrile conditions, as an expectorant and for all the uses of

and without doubt, the period at which those processes have ceased to operate—in other words, the exact time at which a person has ceased to be infective; and (3) that patients who are capable of disseminating infection a week or so after their return home were necessarily, and in all cases, also infective at the time of their leaving hospital. However, these appear to be very large assumptions—assumptions, indeed, which involve certain important but difficult considerations in regard to the natural history of scarlet fever—to which I propose to refer presently. Similarly, notwithstanding that "return" cases have doubtless sometimes been due to imperfect arrangements at hospitals for the disinfection of the patients' effects, or to the fact of patients having been allowed, through careless administration, to take with them on returning home some infected book or toy, yet the circumstance that "return" cases occur in connexion with hospitals which, judged by our present standards, must be regarded as efficiently equipped and administered, makes it impossible, so it seems to me, to ascribe all cases of the sort to culpable negligence in these respects. The practice, indeed, of allowing patients on admission to bring nothing with them but a night garment, which is destroyed at the hospital, fresh clothes being sent from the home on the day of, and for the purpose of, their discharge, does not seem to entirely prevent the occurrence of "return" cases, even though such fresh clothes are sent direct to a suitably constructed discharging house, or "out-bathing place," and though every practicable precaution is apparently taken, short of the absolute sterilisation of the discharge nurse, to prevent these clothes from becoming infected on the hospital premises. Further, as far as I am aware, no relation has at present been made out between the character of the procedures adopted at different hospitals in regard to the discharge of patients therefrom and the occurrence in connexion with such hospitals of so-called "return" cases. Indeed, so far as importance can be attached to a single observation extending over a comparatively short space of time, the experience of Glasgow in this respect is of some interest; for it appears from the paper by Dr. Chalmers, to which I have already referred, that during the year 1894 the percentage of "return" cases to dismissals was practically identical at the two principal isolation hospitals there, notwithstanding that, as he shows, "patients dismissed from Belvidere are subjected to a carefully designed system of bathing in a separately constructed 'clearing house.' ..... At Parliamentary-road Hospital there are no discharging-rooms, and the ward bath-rooms (which are to some extent liable to harbour infection) have to be used." It would by no means be safe to infer from this experience that a properly arranged discharging-house involves a needless expenditure and that it does not in some measure tend to diminish the occurrence of "return" cases. I have quoted the experience only as being consistent, as far as it goes, with the view that defective administration of the sorts in question hardly affords an adequate explanation of any large proportion of the total of "return" cases met with. The kindred suggestion which ascribes "return" cases to insufficient bathing of the patients during the later weeks of their detention in hospital or to the omission of the frequent application to their bodies of solutions believed to possess some disinfecting quality, must for the present, it appears to me, be put aside on similar grounds. I am not aware of any sufficient evidence that the occurrence of "return" cases has been prevented by the use of any particular application of the kind, and it can hardly be suggested that the generally admitted need for frequent bathing is systematically neglected at our best fever hospitals, or that the employment of any practicable means of ridding the surfaces of the body of infective material would not be adopted were any such means known of.

Coming next to the explanations of the other class to which I have referred, there can be little doubt that the occurrence of a fresh case of scarlet fever in a household shortly after the return of a patient from hospital is sometimes a mere coincidence, the fresh case being really due to other causes, such as defective disinfection of the dwelling by the sanitary authority, or to some outside source of infection; and that such may be not infrequently the case seemed to me to be indicated by an experience which recently came under my own notice. In that instance a relatively serious number of so-called "return" cases of scarlet fever occurred during a particular period in connexion with a country isolation hospital; so many, indeed, as to at first sight represent hospital isolation, as there carried out, in a very unfavourable light in regard to the limitation of the spread of the disease as compared with home isolation. The information obtained, however, sufficed to show that during the period in question the households within this hospital district from which patients were sent to hospital suffered as a class much more heavily from secondary invasion—apart altogether from the so-called "return" cases—than the households in the same district in which patients were retained at home throughout the whole period of their illness—a fact, no doubt, partly due to the circumstance of the former being households of a less well-to-do kind than the latter, and in part also to the further circumstance that the hospital class of households comprised on the average a larger proportion of persons at susceptible ages than the home isolation class. Certain facts, however, appeared to indicate that neither age distribution nor social condition sufficiently accounted for the greater incidence of secondary invasion, of kinds independent of hospital operations, upon the hospital class of households than upon the home isolation class—the inference from which would seem to be that some other factor or factors of scarlet fever production had operated more actively upon the former class than upon the latter. And, so far as the information went, it afforded the suggestion that one factor of the kind in question had perhaps been furnished by attendance at particular schools. On the whole it appeared to me probable that some unknown proportion of the so-called "return" cases had in this instance been due, not to the return of the patients from hospital, but to the cause or causes which had contributed to the excessive incidence of secondary invasion generally upon households of the hospital isolation class. This, I venture to think, is an aspect of the matter that is worthy of further study as opportunity offers, and in this connexion the possible influence of school attendance in its relation to alleged "return" cases is perhaps especially deserving of attention. The possibility of alleged "return" cases being part and parcel of a milk outbreak should also of course be borne in mind.

Proceeding with my review of the several explanations to which I have referred, it may, I take it, be concluded that some few of the so-called "return" cases are attributable to the unpacking of some imperfectly disinfected garment in preparation for the return of the patient from hospital—perhaps, as has been suggested, some comparatively new garment which had been intentionally withheld from disinfection lest it should be damaged by the process. But so far as my experience goes it has not appeared to me that variations in the occurrence of "return" cases are so closely related to variations in the efficiency with which the disinfection of dwellings and their contents is carried out as to suggest that such cases account for a large proportion of alleged "return" cases. Thus in the instance to which I have just referred as having recently come under my notice, the largest number of "return" cases occurred during the first of three succeeding years. At the end of the first year considerable improvements were adopted in one of the constituent districts of the joint hospital district concerned in regard to the measures taken for household disinfection. A steam disinfecting apparatus was provided, and, as I was informed, very special care was taken to secure the thorough disinfection of all articles which could be thought of as having possibly been infected by patients prior to their removal to hospital. Subsequently to the adoption of these precautions a considerable diminution occurred in the number of "return" cases heard of in this constituent district, which might certainly at first sight have been attributed to improved household disinfection; but that the whole of this diminution was not so brought about seemed clear from the fact that a diminution in the number of "return" cases occurred coincidently in the other constituent districts where similar improvements in disinfection procedures had not been carried out. On the whole, then, there can, it appears to me, be little doubt that a proportion of alleged "return" cases are really due to infection in some way reintroduced into the dwelling by the returned hospital patients themselves, and I must confess to having some doubt as to whether the view that such patients operate merely as mechanical carriers of infection by lodgment of infected material in the hair or by retention of such material in the lungs or the aural or nasal passages can be regarded as sufficient explanation of the facts as observed. At all events, at the joint hospital I have just alluded to I was assured that special care was taken in regard to frequent washing of the hair, and in order to minimise the risk of recently discharged patients infecting other persons by means

Digitized by Google

of infective material mechanically carried in their lungs or elsewhere it was the practice for all patients to pass a fortnight prior to their leaving hospital in a detached convalescent block specially provided for the purpose, except in cases where arrangements could be made for sending them to reside for a period in cottages in which there were no children. Finally, when they did return home a printed notice was given to their relatives warning them that the patients should for a time, as far as possible, be kept apart from other persons.

No doubt the "infective breath" theory presents difficulties, since it is impossible in the present state of knowledge to estimate its influence; but, while admitting its probable operation in an unknown proportion of cases, it would, I venture to think, be straining it unduly to regard it as a sufficient explanation of "return" cases generally.

If I am right in the views I have expressed, it follows that some share of so-called "return" cases owe their origin to the actual infectiveness of recently returned patients from isolation hospitals, though it seems to me unlikely, for the reasons I have stated, that the fact of such patients returning home in an infective condition can, as a general rule, be attributed to culpable negligence on the part of the medical officers of such institutions; and if that is so it indicates very clearly our need for further knowledge in regard to the pathology of the infectiveness of scarlet fever. Only in proportion as the processes by which infection is given off are clearly understood will it be possible to recognise the termination of those processes. According to a time-honoured and widely distributed belief, the infectiveness of scarlet fever is mainly associated with the process of desquamation. This belief, which is still generally held by the medical profession, recently received support from the Report of the Committee appointed by the Clinical Society of London to investigate the Periods of Incubation and Contagiousness of certain Infectious Diseases, in which it is laid down as regards scarlet fever that "infection certainly persists as long as there is any desquamation." That a belief so widespread, not only among the public, but also among those specially trained in the observation of disease processes, is without foundation seems in a high degree unlikely. There appears, however, to be a growing tendency among certain experienced observers to attach less importance to this source of infection, especially during the later stages of convalescence. That apparently susceptible persons do not necessarily contract disease upon being associated with desquamating scarlet fever patients is well illustrated by the significant experience recorded by Dr. Priestley in a paper read by him before the Epidemiological Society in March last, from which I learn that, owing to an outbreak of small-pox at Leicester, "not less than 120 children in various stages of desquamation after scarlet fever were sent to their homes," and that "no single second case occurred at any of these houses," although Dr. Priestley, in his capacity of medical officer of health, "carefully watched them for three months"; and many of us have probably met with experiences of an allied character, though on a smaller scale. It would be rash indeed to conclude from such negative evidence that the process of desquamation is never attended by infective property, especially in view of the weight of opinion and experience on the other side, and I would not for a moment countenance any relaxation in our present custom of urging isolation so long as any desquamation exists, pending at least a fuller knowledge of the pathology of infectiveness in this disease. But it does appear to me that the whole matter requires very careful study, and it seems at least likely that, whatever may be the part played by desquamation in this respect, we have hitherto underrated certain other modes by which the infection of scarlet fever is disseminated. I refer especially to catarrhal conditions of the nose, ears, and especially of the throat. In so far as it is safe to attach importance to the analogies between scarlet fever and diphtheria, it would appear not improbable that the throat plays an important part in the spread of the former disease, and the fact of this channel of infection not apparently being kept more prominently in view may possibly be due to an exaggerated importance attached to desquamation. For instance, it is not unlikely that in endeavouring to trace the origin of fresh cases of scarlet fever the discovery of traces of desquamation upon a recently recovered patient is often in itself regarded as a sufficient explanation of infectivity, and no further sign is sought, whereas, had examination been extended to the throat, other evidence of infectiveness might have been detected. This appears to be a matter that should be carefully borne in mind in connexion with the study of "return" cases of scarlet fever.

In view, also, of recent researches in connexion with enteric fever, the possible infectivity of the urine of scarlet fever patients would appear to be deserving of attention.

As regards practice, it is easy, however, to say that infectiveness must be presumed to exist so long as any desquamation or any catarrhal condition of the nose, ears, or throat remains; but so far as the prevention of "return" cases is concerned this dictum is by no means altogether satisfactory, for not only are some of the lesions in question apt to become so chronic that the continued isolation of the patient is obviously impracticable, but experience, unfortunately, seems to show that they sometimes recur, and may not, perhaps even then be without powers of infectivity. This possibility of a recurrence of lesions which may possess infectivity is one of considerable importance in connexion with the subject of "return" cases, and is one which should be carefully held in view in passing judgment upon questions of hospital administration in this connexion. Whatever may be the significance of the fact in regard to the infectiveness of scarlet fever, there can, I think, be little doubt that the process of desquamation, although apparently complete, may be again renewed. And the same appears to be true in regard to the other lesions enumerated. Unfortunately, there seems to be little immediate prospect of bacteriology affording that measure of assistance in determining the infectivity or otherwise of such recurrent manifestations in the case of scarlet fever that it promises in regard to diphtheria, but that appears to be an additional reason for close study of the matter in its clinical aspects, and the subject is one upon which I would especially invite the opinions of members of the Epidemiological Society.

I should next wish, by way of suggestion, to briefly direct attention to certain considerations which may perhaps have a bearing upon the occurrence of "return" cases of scarlet fever. In the series of cases to which I have already on several occasions referred there appeared to me to be some indication of the operation of a seasonal influence, the "return" cases occurring most frequently, relatively to the number of dismissals, in connexion with patients who had been discharged during the latter half of the year. I also noted that, relatively to the number of dismissals, such cases occurred most frequently during the rise of the epidemic. It would be unsafe, of course, to draw definite conclusions from experiences of so limited a character, but, so far as they go, they are not inconsistent with the notion that the occurrence of "return" cases may be in part regulated by variations in the infectivity of scarlet fever, or the receptivity of individuals at different times; including perhaps cyclical variations extending over considerable periods such as those to which Dr. Whitelegge has so ably directed attention in respect of certain indigenous diseases. In any case these appear to be questions worthy of attention in the future study of "return" cases of scarlet fever.

A matter of more immediate practical importance upon which also more extended observation is required is the possible operation of overcrowding of hospital wards as a factor in the production of "return" cases. As a result of his investigations in Glasgow Dr. Chalmers appears to have been led to the conclusion that sustained overcrowding of wards does conduce to the occurrence of such cases, and I have myself seen reason to regard overcrowding with suspicion in this respect. Whether its operation, if it does operate in the direction suggested, is due merely to the circumstance that the lungs of the patients leaving overcrowded hospitals are charged with more highly infective air than would otherwise be the case, or whether the surcharging of the ward atmosphere with infective material tends in some way or other to prolong the period of infectiveness of patients residing therein, owing perhaps to their undergoing slight reinfections, as suggested by Dr. Boobbyer, are difficult questions. In regard to the matter Dr. Chalmers remarks that "it would appear that, apart from the possible return of readily recognisable conditions such as desquamation, &c., after dismissal, there is a constitutional effect produced which renders the discharged convalescent a danger to susceptible persons who may be brought into close contact with him. That this results from saturation of the system is, I think, clear; but whether it is due simply to delayed elimination or to constant breathing of a saturated atmosphere by the convalescent, is matter for conjecture." Dr. Chalmers further refers to the fact, brought out by Dr. Sweeting, as to the increased frequency in the occurrence of albuminuria which

Digitized by Google

results from the aggregation of acute cases of scarlet fever as perhaps bearing indirectly on the point in question.

Before concluding there is one point in regard to the investigation of "return" cases upon which the opinions of members of the Epidemiological Society would be very helpful. I have frequently referred to such cases as occurring shortly after the return of patients from hospital. In statistical inquiries into the matter, however, it will usually be necessary to fix some time limit within which cases occurring after the return of patients may be reasonably classified as possible "return" cases, those occurring later being excluded on the ground of their being more probably due to fresh sources of infection; and the question is as to the time limit that should be adopted. This has sometimes been fixed as twenty-one days, and I think it will be agreed that if we err in adopting that period we err on the side of liberality. I observe that 93 per cent. of Dr. Chalmers' cases, which seemingly included all cases heard of, occurred within a fortnight after the dismissal of the patients from hospital; and it has also to be remembered that the period of incubation of scarlet fever is usually less than three days, and practically always less than eight. On the other hand, it of course by no means follows that a fresh case became infected immediately on the arrival of a hospital patient in the dwelling, especially if such case resulted from a recurrence of infectivity on the part of the hospital patient. On the whole, therefore, I am disposed to think that the period of twenty-one days, if somewhat liberal, is perhaps a not unreasonable one for statistical purposes. But, besides what I may call this "far-time limit," a "near-time limit" will also be required. In this respect it would perhaps be sufficient to exclude all alleged "return" cases occurring on the day of arrival of the patient from hospital.

Briefly summarised, the view which I have endeavoured to introduce is that, although a certain proportion of "return" cases may of course at divers times and places be due to carelessness in the discharge of patients or to some other form of culpable maladministration, whether on the part of the hospital officials or of those responsible for the disinfection of the patients' dwellings and effects, there are nevertheless in all probability some more obscure factors at work—factors perhaps closely bound up with the natural history of scarlet fever.

ON THE CAUSES OF BRADYCARDIA.

BY ALEXANDER MORISON, M.D., F.R.C.P. EDIN.,
PHYSICIAN TO OUT-PATIENTS, GREAT NORTHERN CENTRAL HOSPITAL; PHYSICIAN TO THE ST. MARYLEBONE GENERAL DISPENSARY.

IT is not unusual to find the importance of disordered action minimised as merely symptomatic of some recognisable diseased condition. Inasmuch, however, as apparently identical conditions may be associated with quite different manifestations of disordered action the latter may deserve separate study. In no branch of medicine is this more so than in the associated diseases and disorders of the heart. The action of that organ may be abnormally retarded, accelerated, or irregular in cases in which the chief local lesion appears to be the same. This disordered action, it may be, in such cases threatens life, and attention to a "mere symptom" may then become the paramount duty of the physician. A correct appreciation of the influence of such disordered action upon collateral phenomena may also lead to a right interpretation of the latter and of the action of remedial agents. Thus the character of the pulse in angina pectoris will be found to vary according as the cardiac action is quickened or retarded. The abnormally slow pulse under these circumstances will usually be found to be associated with an abnormally full left ventricle, and the retarded action of the latter, with the projection into the arteries at rare intervals of a large quantity of blood, which may impart fulness and a degree of softness even to an atheromatous vessel, which, less filled, would convey the impression of hardness and smallness. The peripheral effect may then be due to the action of the central organ and the modification of the pulse by medicines—a result of remedies acting directly upon the heart and not influencing it solely by changes in the peripheral circulation.

It is not my object in this paper to discuss all the questions of scientific and practical interest bearing upon abnormal retardation of the heart's action, but, limiting myself to the etiology of that condition, to endeavour to arrive at the present position of the question of bradycardia and the most probable lines upon which its further elucidation is to be sought. Our own countrymen, Stokes and Adams, were pioneers in this field; to a German (Grob) we owe the term "bradycardia," now generally adopted; and valuable contributions to the subject have been made in France. My own experience of the condition has accidentally been considerable, and has evoked the interest which I take in the matter.

Although statistics, to be of value as such, require to represent a large number of carefully considered facts, the *sexual element* in persistent bradycardia appears to be important. Of 37 cases which I have examined 31 occurred in males. This is not a large number to have examined, but the preponderance of the male sex which they show in those thus affected agrees with the results obtained by Grob,[1] who also found that in 140 cases of bradycardia of all kinds, persistent and transient, with and without symptoms, no less than 131 occurred in males and only 9 in females. Riegel[2] also notes this disparity. The belief is, therefore, justifiable in the meantime, until statistics prove the contrary, that the constitution and circumstances of the male more frequently result in bradycardia than do the like conditions in the female. Nor is this in accordance with the general liability of the sexes to cardiac disease, for statistics on a large scale (*vide* the Registrar-General's reports) show that woman is, on the whole, more prone to heart disease than man. In this respect the sex ratio of bradycardia resembles that of angina pectoris, which is considerably more common among men than among women. The *age* of patients suffering from persistent bradycardia in the cases collected by me was as follows:—

Under 20 years, 1 case.	Under 60 years, 6 cases.
,, 30 ,, 2 cases.	,, 70 ,, 10 ,,
,, 40 ,, 2 ,,	,, 80 ,, 7 ,,
,, 50 ,, 7 ,,	,, 90 ,, 1 case.

Thus, of the 36 cases in which the age was stated 29 occurred in the thirty years from the age of fifty, when average humanity may be said to be well past the meridian of life, to eighty, when the majority have terminated their existence. This is the period of gradually exhausting energy and of organic degeneration. The age of a man has been stated to be just that of his arteries, and the examination of a series of sphygmograms from youth to age exhibits a normal retardation of pulse, with heart-force increasing to meet the rising arterial pressure and then flagging under the burden of the increased labour, as shown by intermission in its action and other evidences of nerve and muscle failure. It is likewise of interest to examine more particularly cases occurring *before* the fiftieth year. Of such in the series noted by me there were six. The case under twenty—fifteen years of age—was one recorded by Strübing.[3] With the exception of being a little short-breathed as compared with some of his companions, the patient, a boy, was regarded in all respects as healthy. The commencement of his persistent bradycardia was immediately preceded by a long run to save time in going to school. Of the two cases under thirty, one, that of a man twenty-four years of age, also recorded by Strübing,[4] occurred in a subject who had undergone his military service without accident, but in whom bradycardia followed immediately upon hard work as a smith—work, however, it may be noted, which he had probably performed for some time, and quite as arduously, without apparent injury. The other case, occurring in a patient under thirty years of age, was that of a young woman aged twenty, the subject of laryngeal syphilis, recorded by Mr. Pugin Thornton.[5] Of the 2 cases in patients under forty one recorded by Strübing[6] was that of a labourer thirty-four years of age who suddenly became unconscious at work when twenty-eight years old, and who, with bradycardia, exhibited evidence of dilated heart. The other, recorded by Dr. Bristowe,[7] and occurring in a man thirty-one years of age, was regarded by him as a case of syphilis of the heart. A case

mentioned by Tripier,[8] which recovered under the use of iodide of potassium, also had a syphilitic history and occurred in a male forty years of age. The same writer[9] likewise mentions the case of a man forty-five years of age who died from syncopal bradycardia, whose necropsy gave a negative result, and who had abused alcohol. The factors apparently playing a causal *rôle* in the case of these comparatively young subjects are those, therefore, which one would expect to find—namely, physical over-exertion and the degenerative influence of venereal disease and the abuse of alcohol.

As regards the *local conditions* associated with cardiac overstrain, it is permissible, in the absence of clinical evidence of gross and permanent disease, to argue from the ultimate recovery of patients that a heart, healthy as to its muscle, may become acutely dilated. In such cases, if muscular disease be excluded, the condition must be attributed to failure from undue expenditure in any form of nervous energy; but Leyden's observations[10] should render us very cautious in adopting this view. Of four cases examined by him after death—cases of acute dilatation from over-exertion in men previously considered healthy, and whose ages ranged from twenty-eight to thirty-five—in three there was fatty degeneration of muscular fibre, and in one fibrosis of the heart. These four cases of acute dilatation were not, however, associated with bradycardia, but with quickened action of the heart, a fact which causes me to remark that none of the anatomical changes associated with bradycardia either in tissue or mechanism is of itself sufficient to account for the retardation of pulse occasionally associated with them. It is much more common to find pulsation quickened than retarded under these circumstances.

Of pathological conditions in the intrinsic, spinal, cerebral, and sympathetic nerves of the heart unfortunately very little is known. In Mr. Holberton's case,[11] which was attributed to injury of the neck sustained in the hunting-field, Liston, who made the post-mortem examination, describes the pneumogastric nerves as being very large, the middle cervical ganglion on the right side as unusually developed, and the medulla oblongata as small and unusually firm. The last observation is interesting in view of other facts mentioned—namely, that the antero-posterior diameter of the foramen magnum was diminished and the atlas ossified to the occipital condyles. M. Huchard,[12] in commenting on this case, suggests that bradycardia may be dependent upon the state of the medulla oblongata. This is, of course, a mere surmise, and it must be remembered that in this case the patient was a gouty *bon-vivant* with an enlarged and dilated heart. M. Huchard further states, with a positiveness which, so far as I know, is not at present justifiable, and with a completeness of generalisation which is picturesque and pleasing rather than convincing, that, "localised in the heart, arterial sclerosis may cause symptoms of angina, in the bulb those of Stokes-Adams disease (bradycardia), in the kidneys those of interstitial nephritis, and so forth."[13] In short, arterio-sclerosis has only to be located anywhere to rule supreme, and he designates the condition "cardio-bulbar arterio-sclerosis" one of the manifestations of his *hypertension artérielle* which all the world has for long known to be an important factor in disturbances and degenerations of the circulatory apparatus, but the recognition of which M. Huchard claims as a special glory. In emphasising his claims in this respect he very amusingly deprecates that *orientation étrangère* which, I presume, is French for the recognition of the work of others.[14] Dr. (now Sir William) Stokes of Dublin, who with his *confrère*, Mr. Adams, may justly be regarded as having first drawn attention, so far as is known, to the occurrence of abnormally slow pulse (and whose priority M. Huchard acknowledges with an *orientation étrangère* which surprises me) from his original observations,[15] was inclined to associate bradycardia with a systolic basic bruit in the aortic area indicative of an atheromatous state in that position. To this view Sir Richard (then Dr.) Quain took exception in his memorable paper on Fatty Degeneration of the Heart,[16] and Dr. Stokes later,[17] referring to Dr. Quain's criticism, states that he had no intention of regarding the aortic conditions as alone causal of slow pulse, but rather that the cause was to be sought in the whole condition of which such atheroma was a frequent expression. While reverently criticising this qualification of the original statement of this great clinician it may be remarked, however, that it is quite possible that the virtual or actual stenosis at the aortic orifice, due to dilatation of the left ventricle or change in the aortic cusps, or to these conditions combined, may have an influence throughout or at some stages of the case in inducing bradycardia. The behaviour of the over-full ventricle of aortic stenosis differs from that due to aortic reflux. In the latter case its action tends to quicken. In this opinion I am supported by Grob,[18] who quotes von Dusch and Marey as believing that such stenosis has an influence in inducing a retardation of the pulse, the latter believing that the heart contracts more rarely the greater the impediment to an evacuation of its contents. In face of impediment it appears to be a law of hollow extrusive muscles like the uterus and the heart to pause, at least for a time, in their action, then to attempt to surmount the obstacle by increased effort, and finally to lapse, if unsuccessful, into sluggish and waning attempts. A study, moreover, of the increasing resistance of the vascular system, which comes with age, shows that the retarding influence of vascular impediment may in a sense be regarded as a general stenosis. The examination of a series of sphygmograms of advancing age makes this very clear, although to induce true and persistent bradycardia other conditions besides senility must be present. While the degenerative cardiac change most frequently observed in the bradycardia of the aged appears to be fatty in character, this clinical sign has also been found associated with the fibrosis of chronic myocarditis. Grob[19] quotes some such cases from various sources. It is known, however, that these changes are much more frequently associated with an acceleration of the heart's action. Finally, the general habit of body of the patient—that is, whether he be stout or lean, whether his abdomen be protuberant or normal—does not seem to influence bradycardia directly, although, like the failure of thoracic, impediment to abdominal respiration may be a subsidiary factor in the case.

Failing, therefore, to find in grosser lesions a sufficient explanation of bradycardia, I shall shortly examine the physiological conditions in which it has been observed. In 3578 cases examined as to pulse-rate Grob[20] found bradycardia to be habitual and normal—that is, physiological—in 6 cases, or in 0·17 per cent. All these occurred in men, whose ages varied from twenty-five to sixty-five and their pulse-rate from 44 to 58 or 60. An habitual pulse-rate of 60 is scarcely bradycardial, but is below the average rapidity. It is of incidental interest to mention in this connexion, as Comby[21] does on Corvisart's authority, that Napoleon I. had a habitual pulse-rate of 40. The occasional epileptiform seizures which he is stated to have experienced may, in view of this fact, have been cardiac and syncopal rather than truly epileptic. Among physiological conditions associated with bradycardia, Grob and others mention the well-recognised case of lying-in women, but inasmuch as this condition occurs likewise in women who have merely aborted, it is probable that bradycardia in these cases may be in great measure the result of reflex inhibition of the heart. It must be remembered, moreover, that the lying-in or pregnant woman has, although the fact is not generally admitted, some normal hypertrophy of the heart, and that pulse tension and tonic contraction of the uterus are post partum directly related. The slow pulse has also, under these circumstances, been hypothetically attributed to the absorption of fat from the involuting uterine muscle. Finally, fasting has been observed to cause a retardation of the pulse.[22] Certain poisons, again, it is well known, produce bradycardia, and the mechanism of this form of pulse retardation is with great probability due primarily to their action upon the nervous system, however much muscular contractility may be ultimately involved.

The predominant *rôle* of the *nervous system* in influencing the pulse-rate is also argued by clinical experience as shown by the acceleration or retardation, the rhythmical or irregular, and the partial or complete, arrest for the moment of the heart's action. In many, although not in all, such cases, there is reason to believe that the cardiac muscle is healthy.

Under normal circumstances cardiac inhibition and acceleration balance one another, and it is thus that the constant variations in arterial tension due to posture, temperature, food, and other agencies are equalised. Under abnormal circumstances it will also be admitted that notable acceleration of the heart's action is a more frequent phenomenon than its retardation. By a succession of short quick strokes the organ endeavours to effect what it cannot normally do with a smaller number. Acceleration may, therefore, be regarded on the whole as a phenomenon of action and redress. Unusual *retardation*, on the other hand, is very rarely physiological, and must be regarded as syncopal in tendency, whether it be transient or persistent. That is to say, the factors, or some of them, which are capable of accelerating the heart's action, are depressed or in abeyance. These factors are a certain character and quantity of blood, a certain state of the coronary circulation and of the cardiac muscle, a certain condition of arterial tension, and a certain state of cardiac innervation and reserve force. Now it is known that a dilated ventricle with an increased blood weight may pulsate rapidly, and that this may occur in the young and in the old alike, in the anæmic and in those whose blood is of normal character. It is known, also, that the heart may be accelerated when the myocardium is degenerated, when the ventricle is dilated and hypertrophied, and when the coronary circulation is unobstructed or partially obstructed. It is known, on the other hand, that certain poisons always retard the heart's action at a certain period of their action through the agency of the nervous system, and it is likewise known that experiment has demonstrated both retardation and acceleration to be directly due to the stimulation of certain nerves. It is, therefore, I think, permissible to conclude that unknown, but not necessarily unknowable, changes in the nervous endowment of the heart are primarily causal of both transient and persistent bradycardia. This conclusion does not, however, exclude the probable correctness of the opinion, based on clinical observation, that with a normal nerve tissue, and even with a normal nerve power, the blood weight and muscular condition of the heart may be such as to prevent that ready response which occurs under more normal circumstances. It is quite conceivable that cases may occur in which the nervous supply of the heart is more damaged than the cardiac muscle and bradycardia be then more dependent upon the state of the former than of the latter; again, that the alteration in the nerve structures may be of such a character and degree that the aid of cardiac muscular degeneration is necessary to produce bradycardia; and, moreover, that the factors in cardiac movement may be so balanced that tachycardia may occur under circumstances in which it would not have surprised us to find bradycardia. Clinical observation renders such an assumption to my mind both plausible and probable, but it is only by a more accurate knowledge of the changes in all these factors, a knowledge which we do not at present possess, that these interesting and important questions can be determined. If, therefore, there be in the intrinsic or extrinsic nerve-supply of the heart any barrier to the normal action of the accelerant nerves, one can conceive a cumulative distension of the chambers of the heart and insufficient activity of its motor nerves settling down into a persistent bradycardia syncopal in tendency, the natural consequence of which is the usually sudden death which closes the record of most cases of this disorder. I am aware of the unsatisfactory character of this largely hypothetical line of argument, but, however unsubstantial surmises of this kind may be, thought usually precedes action, and conception fruition, and, in so far as these remarks may be suggestive of the direction in which an answer to these problems is to be sought, I respectfully offer them for consideration.[23]

Professor Dehio of Dorpat, in an interesting and practical paper on Bradycardia and the Action of Atropin on the Sound and Diseased Human Heart,[24] came to the conclusion from a study of the effects of atropin in what he terms "cardial and extra-cardial bradycardia" that the explanation of slow pulsation has to be sought in the heart itself, as the inhibitory function of the vagi must be supposed to be abolished by the atropine. He admits that we are at present ignorant of the nature of that which causes the bradycardia, but suggests that it is due to nutritional changes in the automatic nerve centres in the heart, dependent in all probability upon local sclerosis of the branches of the coronary arteries leading to such centres. Inasmuch, however, as persistent bradycardia is met with at an age when the presence of such coronary sclerosis is highly improbable, his explanation only covers a certain number of cases. It must, however, be remembered that it is not only atropine which fails to accelerate such hearts, but that trinitrine, exertion, and other stimulants are equally ineffectual and that in the case of the latter agents there is no reason to believe that the vagi are placed out of action. I prefer, under these circumstances, to state vaguely and generally that the fault may lie in the accelerant as well as in the inhibitory system of the heart, and that the elucidation of this fault will require a patient investigation of the accelerant and motor tracts from their origin to their termination and in their relation to the semi-independent intrinsic nervous system of the heart. Cardiac neurology has probably as brilliant a future as neurology in general, and its increased investigation by pathologists is much to be desired. Parenchymatous changes resembling those in peripheral neuritis have been found by Vincent in the cardiac plexus in a case of heart failure after diphtheria—a failure of the heart which I have known to be bradycardial before the final syncope—but the record of such investigations is too rare.[25]

Upper Berkeley-street, W.

[23] Since writing the above I find in Pflüger's Archives for Physiology (Band lx., p. 491) gratifying experimental corroboration of these surmises, based upon clinical observation by myself and others. As the general result of experiments on rabbits, Dr. H. E. Hering is led to the conclusion "that the increase in the frequency of the heart's action during muscular exertion is chiefly connected with the integrity of the accelerator nerves, and that the increase of irritability of the heart-hastening nerves which occurs in normal animals is assisted by a simultaneous decrease in the irritability of the heart-slowing nerves." May not the converse also be true?

[25] THE LANCET, March 23rd, 1895.

A CASE OF MYCOSIS FUNGOIDES.

By LESLIE ROBERTS, M.D.,
DERMATOLOGIST TO THE ROYAL INFIRMARY, LIVERPOOL.

PERHAPS there is no cutaneous disease in which we meet so many phenomena strange and not understood as in mycosis fungoides. The rarity of its occurrence, its apparent chronic innocent benignness passing into swiftest malignancy, our ignorance of the nature of the disease and the means of controlling it, the pathological problems which arise from it—these are not merely fitted to awaken scientific curiosity, but impose on those who are privileged to observe them the duty of contributing something, if possible, to their elucidation.

The patient, a spinster, was admitted into the Royal Infirmary, Liverpool, under my care on Nov. 5th, 1894. The only fact of etiological importance in her family history was that both her mother and sister had died from phthisis. Her mind was too dull and confused to give any clear, intelligible account of herself and the disease. Lately her strength and nerve had been severely tried by nursing her father, who was bedridden, suffering from paraplegia with incontinence of urine and fæces. The first appearance of her skin disease was referred by her somewhat indefinitely to four or five years ago, when a moist eruption appeared on the left arm, which resisted all treatment and eventually disappeared spontaneously. Later, redness and swelling were noticed in the right leg, and later still on the right wrist, where a "boil" developed which was lanced, with subsequent relief. This irregular state of cutaneous health continued till about the beginning of 1894, when the head and face became affected with a moist eruption. The patient was treated for eczema, but with no benefit. During the year the entire cutaneous surface became affected with a dry, pruritic, desquamative dermatitis. About three or four weeks before her admission to the infirmary small tumours, mistaken for boils, arose in various parts of the trunk, arms, and face. Her health was failing when by medical advice she came under my care on Nov. 5th, 1894. Inexact and obscure as this history is, we may note that during the early years of her illness the skin lesions were superficial, apparently benign, and took the form of a dermatitis. This is the rule in mycosis fungoides. The pre-tumour "eruption" is polymorphous—erythematous, eczematoid, and lichenoid. Philippson's

Digitized by Google

histological researches on the nature of these "eruptions" show that they are not at all of the nature of a dermatitis, but are veritable intradermic neoplasms confined to the papillary and subpapillary layer of the derma and associated with some increased cell activity in the epidermis. On admission the patient was found to be a fairly well-nourished woman of medium height, but in poor health. The skin over the entire body, head, and limbs was changed in respect of colour, density, integrity of parts, and configuration. The scalp was covered with excoriated spots, and much hair was lost; what remained was dry and lustreless. The surface of the scalp was desquamating freely. The face was red and moist, the condition resembling a weeping eczema; the discharge stiffened linen. The eyelids of the left eye were red and swollen, and could only be partially opened. A livid-coloured tumour extended from the outer canthus of the left eye to the left ear, part of the auricle of which it involved (Fig. 1). It was hemispherical in shape, slightly irregular, ulcerated in parts, moist with discharge, and soft and elastic to the touch. A flat tumour the size of a florin was situated on the forehead;

FIG. 1.

Showing left side of face; a livid-coloured tumour extends from outer canthus of left eye to left ear.

its margins sloped into surrounding unhealthy-looking skin. The discolouration of the trunk resembled, somewhat, that of a typhus skin, and was covered with fine scales harsh to the touch. The right breast was in part red and covered with scabs; several tumours, varying in size from a hazel nut to a pigeon's egg, arose discretely from the front and back of the trunk. The neoplasms arose gradually out of the surrounding skin and sloped upwards to a flattened apex, somewhat like a cushion pushed up in the centre. They were dull red in colour and soft and elastic to the touch; some were discharging an offensive-smelling pus, and others were ulcerating. There were numerous scab-covered points scattered all over the back of the trunk. The skin of the arms was thickened and rough, with numerous scab-covered papules. There was induration of the skin of the fingers, which were bent on the palm, and also considerable hyperkeratosis of the palms. (Fig. 2.) The nails were more or less affected by loss of lustre, flattening of convexity, and prominent longitudinal ridges. Both hands had a withered, dried-up appearance. The legs were considerably swollen and eczematoid in appearance; the skin was indurated and covered with thin scabs of yellowish colour. There was well-marked œdema of both dorsal surfaces of the feet which were covered with thin scabs; the outer side of the right foot was excoriated. The nails of the toes were much deformed and partially destroyed. Itching was very severe at times, but seemed to be intermittent in its attacks. The cutaneous lymphatic glands were not enlarged. The pulse was 100, the temperature 99·8° F., and the respiration 18. There was no cough or expectoration. The urine was slightly alkaline, of a specific gravity of 1022, with a slight cloud of phosphates on boiling.

To those acquainted with the features and natural history of this disease the diagnosis in this particular case presented no difficulty. The difficulty of diagnosis occurs in the early stage, when the pruritic "eruption" is apt to be mistaken for eczema, psoriasis, or pityriasis. If circumstances permit of the suspected eruption being microscopically examined, as Philippson suggests, the embryonic cellular, fibrillar condition of the upper layer of the derma, with numerous mitoses, is sufficient, according to this observer, to diagnose the disease even in this early stage.[1] The patient lived two months after admission to the

FIG. 2.

Showing withered, swollen hands, with bent fingers.

Infirmary. During this time the temperature fluctuated in a manner very similar to that of chronic pulmonary tuberculosis. There were intervals of exacerbation or exaltation of temperature, with periods of depression when the temperature was normal or subnormal. The temperature rose in the evening and fell in the morning. During the last month the patient had a moist cough and complained of great pain in the right side. Sleep was broken and disturbed a good deal by the feeling of heat and flushing, especially in the head, by paroxysms of itching, and by pain more or less constant. The condition of the tumours was constantly fluctuating; indeed this is one of the most remarkable features of the disease. Growth of the swiftest sort was followed by involution equally rapid. Thus the tumour on the left side of the face was the size of a large orange at the time of her admission. In sixteen days it formed a huge tumour involving the entire side of the face and part of the scalp, and almost smothering the nose. Its involution was very rapid, and just before death it disappeared completely, leaving no cicatrix and but few traces of its previous

[1] For exact histological details of this stage see the original article by Philippson. Annales de Dermatologie et de Syphilographie, 1892, p. 581.

Digitized by Google

existence. Some of the tumours on the trunk suppurated, some ulcerated, and others involuted without breaking. The growth and involution of the larger tumours were accompanied by a profuse discharge with an extremely offensive odour. Another remarkable feature about the case—as, indeed, about every case of mycosis fungoides—is that no drug seemed to have any influence over its career. Carbolic acid lotion (1 in 20) was injected into several parts of the largest tumour to the extent of one drachm. It produced shrinkage and sloughing in the area injected; but as it seemed rather to aggravate the offensive discharge, which constantly oozed from the tumour, the "remedy" was soon abandoned. Pyrogallol was applied in ointment form to some of the smaller tumours, but with no benefit. A temporary amelioration of the general or diffused condition of the skin of the trunk and limbs was brought about by the change in the patient's mode of living. When removed from the fatigue and anxiety of nursing, a few days' rest in bed, with daily warm, mild, sulphur baths, had the effect of diminishing the eczematoid symptoms very considerably. Opium was given on account of the pain and uneasiness. Administered by the mouth it had but little effect, but more when morphia was injected subcutaneously. Six days before death the whole of the left arm, from the wrist to the shoulder, suddenly became swollen, hot, and of a livid colour. There was a small tumour in the axilla. The following day the swelling had gone. On the morning of Jan. 8th, 1895, the temperature suddenly rose to 103·6°, and a few hours later the patient quietly died in a state of unconsciousness.

Necropsy.—At the post-mortem examination, performed by Dr. Abram twenty-three hours after death, the body was found to be emaciated. The skin over the whole body was dry and shrunken—as it were, mummified—and of a dusky hue. There was no trace on the face of the tumours which had previously existed there. The lymphatic glands were not enlarged either in the integument or in the mesentery. There was no enlargement of lymphatic follicles in the stomach or in the ileum. The spleen weighed 5 oz. The kidneys were slightly injected. The liver weighed 52 oz. and was paler than normal. In the right lung there were pleural adhesions posteriorly, and the pulmonary tissue was emphysematous. There were some pneumonic patches breaking down in the right apex. The weight of the lung was 38 oz. The posterior surface of the left lung was covered with tough lymph, and the parietal pleura was injected. The lower lobe contained a large cavity with a smooth lining filled with puriform blood-stained fluid. Cover-glass impressions stained with fuchsin and methyl blue showed abundant tubercle bacilli. The heart was normal except for a little atheroma of the mitral valve. The necropsy confirmed what was known before—namely, that this neoplasm does not form secondary growths in the interior of the body. It is essentially a disease of the derma arising from the connective tissue cells by active proliferation. The tuberculous lesion of the lung must be considered as a coincidence and probably caused the fluctuating temperature.

What is the nature of mycosis fungoides? Is it produced by a definite micro-organism? These questions intrude again and again on our ignorance and have been variously answered. I shall briefly relate my own experience and then allude to the results of others. During life a small portion of the large tumour was excised, and inoculations were made by Professor Boyce in the following way. The surfaces of the piece of tissue were sterilised by a red-hot cautery, and a sterilised fine-pointed glass tube was pushed into the interior, some juice sucked up, and then transferred to four peptone agar and two agar beer-wort (artificial) tubes. The peptone agar tubes were placed in an incubator at 36° C., and the two latter in another incubator at a temperature varying from 25° to 30° C. After two months growth was found in only three of the six tubes, but these three contained specimens of the same organism. To the naked eye they resembled the staphylococcus albus, a vegetation which, when grown on nutrient gelatine, looks like a drop of white paint. The organism in question, however, differed from all the pus organisms in respect of its rate of growth, which was exceedingly slow. In two months the vegetation attained at 36° C. a diameter of 2 mm., and at 30° C. less than half this. The fungus in question was a micrococcus 0·5 to 1 μ in size, not forming zoogloear masses while living, but isolated or attached in twos and threes, and exhibiting active Brunonian movement. Blood examined before death did not contain cocci. It was taken from a finger tip remote from the tumour. I am inclined to regard this micro-organism as adventitious and not pathogenically connected with the disease. There is very little uniformity in the results of other investigators. Rindfleisch found streptococci within the vessels, but the value of this evidence is vitiated by the fact that his patient died from septicæmia. Hochsinger and Schiff purport to have found micro-organisms within the cells of the neoplasm. Without disputing the trustworthiness of their observations (although such observations are attended with the greatest difficulty on account of the granular condition of the protoplasm) we require evidence, which now is wanting, before we can accept their conclusions regarding these organisms. On the other hand, many observers have failed altogether to discover, after careful and proper research, any micro-organisms either in the blood or in the cells of the neoplasms. This was the case in Unna's patient, investigated by Philippson, and to this negative list may be added the names of Payne, Köbner, Dönitz, and Lassar.

With regard to the histology of the case it should be noted:—

1. *Skin free from tumour and forming seat of "eczematoid eruption."*—The portion of skin was taken from the outer side of the thigh. The primary and essential changes had taken place in the papillary body (including the portion immediately beneath the papillæ). This portion of the derma was differentiated from the subjacent part by a sharp line, and after hæmatoxylin staining became striking and conspicuous. The normal fibrous tissue had been replaced by a cellular neoplasm, not by cell infiltration, for there was not a trace of inflammatory action, consisting of cells derived from the pre-existing connective tissue cells, round or oval in shape and nucleated. The fibrillæ were sparse and delicate. The papillæ were narrower and a little longer than normal. The most conspicuous feature in the pars reticularis was the rhomboidal meshwork of hypertrophied elastic tissue. This was very noticeable even without special staining. The elastic meshwork was filled with a granular matrix which stained with carmine. The white fibres were inconspicuous. The connective tissue corpuscles were increased. The epidermis was slightly altered. The cones were broader and a little longer than usual in this position and the corneous layer somewhat thicker. The sweat glands appeared to be normal. There were no follicles in the piece of tissue examined.

2. *Skin from the palm in which the epidermis was very much hypertrophied, but throughout the whole clinical history was free from "tumour" formation.*—(*a*) *Epidermis:* This was about three times the average thickness; the hyperplasia was noticeable in all the layers. The germinating layer consisted of two or three rows of cells whose nuclei were more deeply stained than those of the superjacent cells. The granular layer was increased in thickness. The prickle cells were swollen and granular; the intercellular spaces were a little wider than normal. The horny layer was enormously hypertrophied and had some peculiar features; the cells in the lower two-thirds of the stratum were enucleated and swollen and separated apparently one from another by shining and refractile clefts. In addition to these intercellular clefts there were numerous irregularly shaped spaces filled with some granular material fixed with absolute alcohol and stained blue by hæmatoxylin. Some of these spaces measure 60 μ in length and about 20 μ in breadth, others were much smaller than this, and others, again, considerably longer. Probably these represented intra-epidermic vesicular collections of fluid, but whether œdematous or inflammatory I could not determine from the microscopical appearance. (*b*) *Papillary body:* The connective tissue cells were much increased, but the fibrillar element was still apparent; it was not so highly cellular as in the specimen taken from the thigh. There was a total absence of cell infiltration. The capillaries were distended and more numerous than in the specimen from the thigh. (*c*) *Derma:* The pars reticularis was not so obvious or the elastic fibres so large as in the specimen from the thigh. The connective tissue corpuscles were much increased in number. Strands of spindle-shaped cells ran horizontally through the derma; they seemed to invest capillaries.

3. *The scalp.*—A portion was selected free from tumour, but otherwise unhealthy. The epidermis was rather thinned than hypertrophied. The papillary body was more or less cellular. The follicles were considerably affected so far as

Digitized by Google

concerned the papillæ and fibrous investments; these participated in the cellular change which affected the papillary body. There was some wasting of the bulb and pilogenic cells, but otherwise the epithelial portions of the follicle appeared normal. A noticeable feature was the very oblique direction of the follicles, which was greatly in excess of the natural obliquity. This oblique direction was likewise taken by the epithelial cones and dermal papillæ. Caustic potash solution had the effect of more or less completely correcting this obliquity. The reticulate arrangement of the elastic fibres was well seen.

4. *Tumour in early stage.*—Elastic tissue enters very largely into the construction of both the early and the late fungating tumours, but I found it rather more plentiful in the young tumours. It was disposed in the form of a meshwork which became very noticeable after maceration of sections in a solution of caustic potash. The only real distinction between the early and late tumours seemed to consist in the closer packing of the embryonic cells in the latter. Bloodvessels were scarce and formed in this respect a notable contrast with sarcomata. As regards the epidermis, my sections did not show the passivity and thinning which Philippson describes. On the contrary, there was a highly irregular hypertrophy of the epithelial cones consisting of granular and unhealthy cells. In some places the cones were enlarged and in others entirely effaced. Cup-shaped depressions in the horny epidermis filled with corneous tissue were noticed in the sections of the fungating tumours.

It must be confessed that the facts of mycosis fungoides are among the dark writings of pathology, and that we wait expectant of the coming interpretation. Viewing my case in the light of the now extensive literature of the subject, it seems that we may deduce the following propositions: 1. There is neither clinical nor histological unity in the picture of mycosis fungoides, but variations of which the limit is not yet fixed. 2. From beginning to end the disease is neoplastic and not inflammatory, the so-called eczematoid lichenoid eruptions are neoplasms *en nappe*.[2] 3. That the papillary body is *conspicuously* differentiated from the derma proper, that the origin of the disease is probably in the papillary body, and that the change consists in an over-multiplication of the pre-existing connective tissue corpuscles. 4. That the rest of the derma is overcellular and that there is an increase in the reticular elastic tissue which is obvious without special staining or maceration. 5. That the disease from the point of view of its evolution and anatomy presents suggestive analogies with embryonic cutaneous tissues and embryonic processes—e.g., rapid evolution followed by rapid involution. 6. That the term "granuloma," being vague and generic, is not a wisely chosen substitute for the name "mycosis fungoides." 7. That there is at present no evidence worthy of confidence for believing in the microbic origin of the disease. 8. That, while the disease is allied clinically to sarcoma cutis, there are many notable differences—thus, the mycosis tumours involute very commonly, and may disappear entirely, leaving a disorganised skin but absolutely no scar; they do not spread into the interior by the veins or by the lymphatics. The chief seat of mycosis is the papillary body, but in sarcomata, according to Funk, we find the densest cell masses in the subpapillary layer, the papillæ, however, being free. 9. That mycosis differs from lymphadenoma (*lymphadénie cutanée* of the French authors) by the fact that the lymphatic glands and spleen are not generally affected, and may be absolutely free from beginning to end of the disease.

Liverpool.

[2] This was first pointed out by Philippson.

ROYAL METEOROLOGICAL SOCIETY.—The opening meeting of the present session was held in the new building of the Institution of Civil Engineers on Wednesday evening, the 20th inst., Mr. R. Inwards, F.R.A.S., President, being in the chair, when a paper by Mr. J. Eliot, F.R.S., was read on "The Origin of the Cold Weather Storms of the Year 1893 in India, and the Character of the Air Movement on the Indian Seas and the Equatorial Belt, more especially during the South-west Monsoon Period." This was really a discussion of the data contained in the "Indian Monsoon Area Charts," the publication of which was sanctioned by the Indian Government for the two years 1893–94.

A NOTE ON

THE THERAPEUTICS OF SALINE LAXATIVE MINERAL WATERS.

BY THOMAS D. SAVILL, M.D. LOND., M.R.C.P.

1. *Habitual constipation.*—When first I took charge of the 250 patients in the Sick Wards of the Paddington Workhouse one of the chief difficulties I had to contend with was the troublesome constipation among them. It was of a very widespread and obstinate kind, apparently the result of some cause or causes acting in common, and after careful investigation the chief of these causes appeared to me to be the routine administration of compound rhubarb pill, which had been distributed wholesale by the attendants. This medication after temporarily relieving the constipation was usually succeeded by constipation more pronounced than before: a chronic constipation which by-and-bye, in the course of a few months, defied all but the most violent purgatives. Of these the following pill is the chief example:—Croton oil, 1 minim; resin of podophyllin, 1 grain; calomel, 2 grains; and extract of Barbadoes aloes, 1 grain. It was known as "pilula fortissima."

This result — succeeding constipation — has been met with in my experience after almost every form of vegetable purgative such as is usually administered in the pill form. The bowels will act two or three times on the next day, and this expenditure of energy is followed by two or three days' inaction. Now this objectionable torpor of the intestines does not, as far as my experience goes, follow the use of natural saline purgatives. For this reason, amongst others, I have largely prescribed them both in hospital and in private practice; and after a course of two or three weeks its effect seems to be to regulate the bowels so that they acquire a habit of acting without artificial stimulation. Indeed, so much more simple and efficacious is this method of treatment that it is a matter of surprise to me that the habit of taking pills should continue to hold the wonderful sway it does in the mind of the general public.

2. *Plethora.*—This method of treatment seems to be specially useful in persons of a full habit of body, who suffer, perhaps, also from the effects of living too well, and under these circumstances it may be continued for long periods of time with none but beneficial results. The habitual administration of a natural saline laxative water in such cases does not produce the irritating effects on the gastro-intestinal mucous membrane which invariably follow constant recourse to pill purgatives. It may be necessary in such cases to administer larger doses, which can be done without fear, and possibly twice a day, continuously.

Nearly a year ago a gentleman aged thirty-four years consulted me for a most alarming epistaxis which had occurred on two occasions. He had for some years been subject to headaches, and these had been particularly severe just prior to the attacks of epistaxis. After careful investigation I could ascertain absolutely no cause except a plethoric habit of body, of which he presented a very marked example. I therefore placed him on a course of matutinal libations of Hunyadi Janos water (half a tumblerful) for a month. He has continued the treatment off and on ever since, and now he declares that he feels quite another man: he is free from both headaches and epistaxis and is much better in health, fitter for work, and lighter in spirits, though his mode of life in other respects has not materially changed. One is tempted to ask why such patients should be sent to Carlsbad and similar places when the treatment could, with the coöperation of the patient, be quite as efficiently carried out at home.

3. *Liver disease and portal congestion.*—"Hæmorrhoids," even in the absence of actual disease of the liver, constitute one of those troublesome minor ailments which may be relieved entirely by this method of treatment, and the soft, easy evacuation which is the invariable result is a great source of comfort to the patient. Congestion of the liver, so frequent in the Anglo-Indian, and which also arises as a consequence of cardiac or long-standing pulmonary disease, often gives rise to uneasiness in the region of the liver, which prevents the sufferer from lying on the right side and may even determine recurrent gastric derangements and transient jaundice (non-obstructive, the stools are even darker than natural). These [illegible] very readily to

Digitized by Google

the same method of treatment. Even in the early stages of cirrhosis of the liver much good may be done by such treatment, which relieves the portal congestion very markedly. I have also employed the same method frequently in cases of catarrhal jaundice, and here it seems to act very beneficially on the mucous membrane of the stomach and duodenum. There is, of course, a very large element of gastritis in such cases, and an appropriate mineral water appears on this account to possess very marked advantages over the use of artificial saline or pill purgatives. Given early in the morning it clears the stomach and the alimentary canal in general of any irritants or undigested food which may be present, and at the same time seems to allay the irritability of the stomach and intestines.

4. *Dyspepsia.*—In atonic dyspepsia the food which escapes complete digestion from day to day undergoes fermentative changes resulting in the production of various irritating products, which not only act as local irritants but may be absorbed into the blood and determine general disturbances of a more or less serious kind. These products of incomplete digestion may be swept out each morning and the irritability of the mucous membrane allayed in the manner just mentioned.

5. *Lithæmia.*—This condition is probably due either to an imperfect elaboration of food in the first stages of digestion in the alimentary canal or to imperfect nitrogenous metamorphosis in the liver, or occasionally, no doubt, to both these causes in association. It is manifested by the habitual deposit of lithates in the urine, and a characteristic headache, on which the researches of Haig have thrown so much light. There are also present a general disinclination for sustained worked, pains in the limbs, irritability of temper, and generally dyspeptic symptoms. In my experience all these symptoms may be markedly relieved by a course of some natural laxative and saline mineral water taken in the morning, combined with the administration of a mixture of bark with dilute nitro-hydrochloric acid, taken half an hour before meals during the day. The one clears out undigested food of the day before, while the other promotes digestion and gives a tone to the alimentary tract.

6. *High arterial tension.*—Reference has already been made to the value of this class of remedy in cases of cardiac disease attended by passive congestion of the liver, but the beneficial effects are not less marked in cases associated with heightened arterial tension, which may be a very prominent symptom in other conditions. As an instance I may mention a man aged forty-five years suffering from breathlessness and with a pulse remarkable for its high tension, who consulted me about six months ago. He had lived freely, but had suffered no illness. The area of liver dulness was slightly increased, the enlargement being apparently due to temporary congestion, seeing that it rapidly subsided under treatment. Transient albuminuria in a urine otherwise normal also suggested simple congestion of the kidneys. The arteries were not notably thickened. There was slight increase of the cardiac area to the left, with a too forcible impulse, indicating hypertrophy of the left ventricle. No murmur was present. The patient complained of more or less persistent headaches. I ordered him bark and alkalies for three days, together with a course of Hunyadi Janos water (one-third of a tumblerful twice a day), and since that time he has taken the water daily in the morning. The results of the treatment were that in the course of a week the blood-pressure fell to normal, and the albuminuria and his other disagreeable symptoms entirely disappeared, not to return up to the present time. He states that he is now in better health than he has been for years past, but he writes to me saying that if he ceases to take his morning dose of water for a day or two the headache returns. It seemed probable that the heightened arterial tension in this patient was due to cardiac hypertrophy, but cases of arterial fibrosis, granular kidney, and gouty and other conditions in which high arterial tension is a prominent feature may be similarly relieved by the same treatment. The most reasonable explanation of its action in this respect is that it dehydrates and purifies the blood.

The value of this method of treatment in various impure conditions of the blood cannot well be over-estimated. The loss of energy so characteristic of prolonged town life is most probably due to deficient oxygenation within the tissues of the body. As a consequence of this a number of excretory or waste products are retained within the body which, if properly oxidised, would be readily excreted. If these imperfectly elaborated products be constantly augmented by incompletely digested food-stuffs retained within the intestines and partially absorbed therefrom, a great additional strain is thrown on the oxidising functions of the body. By the treatment suggested not only can these be swept out of the intestines, but by dehydration of the blood, the blood itself, especially that of the portal system, is purified.

7. *Anæmia.*—Pupils of the late Sir Andrew Clark will remember that he used to regard constipation as the main cause in this disease. As a result of the costiveness, ptomaines and several imperfectly formed products of digestion were absorbed into the blood and overtaxed the oxidative processes of the body. At any rate, cases of chlorosis are often greatly improved by free relief of the bowels even without the administration of iron.

8. *Method of administration.*—As to which of the various natural saline laxative waters is the best to accomplish these ends there may perhaps be different opinions. The three mineral waters chiefly available for the above purposes are Carlsbad (Sprudel being the favourite spring), Friedrichshall, and the Hungarian water Hunyadi Janos. The analysis of these three waters is here given for comparison in terms of grains per gallon, only the principal ingredients being given:—

—	Carlsbad (Sprudel).	Friedrichshall.	Hunyadi Janos.
Sulphate of sodium	200	465	1578
Sulphate of magnesium	—	395	1568
Bicarbonate of sodium	90	—	47
Bicarbonate of calcium	20	—	55
Chloride of sodium	87	611	119
Chloride of magnesium	—	302	—
Sulphate of calcium	—	103	—
Silica	10	3	—
Analysis by	Gottl.	Liebig.	Bunsen.

All three contain a small quantity of CO_2 when first drawn from the source. Carlsbad water I have found useful in cases of genuine gouty or rheumatic affections of the joints, probably on account of the relatively large proportion of alkaline carbonates and sodic chloride contained. The dose, however, must be one or two tumblerfuls once or twice a day. Neither the Sprudel nor the other spring is very strong in laxative salts (about 13 grains of sulphate of soda in a tumblerful), and it has not proved so efficacious in the various conditions referred to as either Friedrichshall or Hunyadi. Friedrichshall contains a higher proportion of the sulphates of soda and magnesia (60 grains to the tumblerful), and is more suited to the present purpose; but it contains practically none of the alkaline carbonates and a very high percentage of the chlorides of sodium and magnesium. It is probably on this account that one cannot give sufficient of it to have a decided laxative effect without producing unpleasant thirst and dryness of the mouth. The usual dose is a wineglassful to half a tumblerful, and this hardly has the desired effect in clearing out the contents of the bowels. It contains, moreover, a fair proportion of sulphate of calcium, which has, if anything, a constipating counter-effect. I have never felt satisfied of the therapeutic value of this last-named salt, though I have had an extensive opportunity of trying it.[1] Friedrichshall water has generally seemed to me to be most useful in renal and urinary cases. Hunyadi Janos water is very rich in laxative salts, containing nearly 200 grains to the tumblerful, or twice and a half as much as Friedrichshall, and thirteen times as much as Carlsbad. It is, I think, the saline laxative mineral water most suitable for the various conditions above mentioned. It is prompt and certain in its action, and does not leave behind it a torpid condition of the alimentary tract. About one-third of a tumblerful or more, adapted to individual requirements, with or without warm water, taken each morning on waking, is generally sufficient to produce a loose, comfortable evacuation of the bowels within two hours, and without the griping which often attends other purgatives. Patients say it is less disagreeable than other waters. It also contains a fair proportion of sodic chloride and the two alkaline salts, which seem to impart to it a mild diuretic action, thus increasing excretion in both directions. It is probably the bicarbonates of soda and lime

[1] St. Thomas's Hospital Reports, vols. xiii. and xiv., 1884–85.

Digitized by Google

which have the beneficial effects mentioned on the mucous membrane of the alimentary canal, and their proportion is just sufficient not to impair the laxative action of the other salts. It is the bicarbonate of lime which seems most beneficial in this respect. To get this local effect on the stomach and intestines about a quarter of a tumblerful with warm water should be given twice a day, always on an empty stomach.

Remarks.—It is not claimed that there is anything very new in the foregoing. The matter is referred to and these experiences are recorded because in my opinion a deeply rooted habit has in this instance been the means of obscuring an improved method of treating several minor but inconvenient ailments, and some more serious ones in their earlier stages. The advantages to be gained by the mineral water treatment over that by pills much more than counterbalance the convenience of carriage, which is the only one that can be urged for the latter; as a matter of fact, it is only on a few occasions that this can be allowed to have any weight.

Upper Berkeley-street, W.

SARCOMA OF SACRUM OBSTRUCTING LABOUR.

BY J. FERGUSON LEES, M.B., C.M. GLASG.

ON Monday, April 22nd, 1895, I was sent for to see a married woman aged twenty-five years, who was suffering from retention of urine, vomiting, and diarrhœa. The patient was in a condition of extreme emaciation and prostration, and obviously very ill. The tongue was slightly furred, the temperature normal, and the pulse-rate 110. The skin was moist, and she complained of cold, clammy sweats. The lungs were healthy. She stated that she was in the ninth month of her pregnancy and had already had three children, the last one having been born fourteen months before. During her previous labours, beyond the fact that they were tedious, nothing worthy of note had occurred. Since the birth of her last child she had not been in good health and had suffered at intervals for the last three months from attacks of vomiting and diarrhœa with colicky pains. She also complained of having partial loss of power in the lower limbs and of suffering from what she described as "sciatic pains" in her legs. The paresis had been first noticed about four months previously, but she had been suffering from the pains in her legs for about eight months. For some days she had had great difficulty in micturition, and during the previous twenty-four hours had been unable to pass any urine. On passing a catheter about two pints of reddish-brown urine, which was highly alkaline and of an offensive odour, were drawn off. She had had some slight difficulty in micturating for the last six weeks, having had to "strain" very much each time urine was passed; but it had only been within the last week that the difficulty had become very great. The patient's health had been very good previously to her marriage, but since the birth of her first child she had always been ailing. The family history was good. On inspection the abdomen was seen to be of a peculiar shape and elongated in a transverse direction, and on palpation the fœtal head was found occupying the left iliac fossa, whilst the body of the child lay almost transversely across the uterus. Per vaginam I found a non-fluctuating, uniformly hard mass lying just within the vulva. This mass occupied the whole cavity of the pelvis, and it was only with difficulty that the finger could be passed between it and the symphysis pubis. The posterior vaginal wall could be traced from the perineum up, in front of the mass. Per rectum the tumour was felt lying behind the rectum and firmly adherent to the sacrum. On April 24th, as labour pains had commenced in the evening, Dr. Ainsley was called in consultation, and on examining per vaginam under chloroform the os was found to be dilated to about the size of half-a-crown. Cæsarean section was determined upon, and the patient was advised to go into the Hartlepools Hospital. She was admitted to the hospital at 3 A.M. on Thursday morning under Dr. Ainsley's care, when she was found to be in a very unfavourable condition for operation, but as the pains were strong and increasing no time was lost in making preparation. The abdomen was rapidly purified, a drachm and a half of liquid extract of ergot were given by the mouth, and five minims of liquor strychniæ were injected subcutaneously. Chloroform was administered and the abdomen opened by the usual incision, six inches long, from above and to the left of the umbilicus to two inches above the symphysis pubis. The abdomen round the uterus having been packed with sponges, an incision about five inches in length was carefully made into the uterine wall, Dr. Macgregor, the house surgeon, pressing on the flanks and sides of the abdomen and pushing the uterus up against the wound and sponges. A slight gush of blood showed that the placenta was beneath the incision. A finger was pushed between the placenta and the uterine wall, and on it the tissue was divided by scissors to its full extent of five inches. A hand was then passed through the placenta and membranes, a foot seized, and the fœtus rapidly extracted and handed to an assistant for him to deal with. The placenta and membranes were swept out, and the uterus was grasped firmly between two sponges, little blood having been lost. The uterine walls were attenuated and flabby, and this, with the absence of contraction, led us to discard the idea of leaving the uterus *in situ*. Dr. Ainsley therefore applied a whipcord ligature low down, put on a Keith's clamp, and cut off the body three-quarters of an inch above the clamp. As an extra precaution the ovarian and uterine arteries were ligatured. The abdomen was sponged out, the stump placed in the lower angle of the incision, and the peritoneum arranged round it. The abdominal wound was sutured and the stump dressed with iodoform and boracic acid. The patient was put to bed in a collapsed condition. A nutrient enema was given and liquor strychniæ injected subcutaneously. The patient never rallied, however, but died four hours after the operation.

Necropsy.—Permission was only obtained to "look at" the tumour. It was found, as had been diagnosed, growing from, and firmly attached to, the front of the body of the sacrum, between the periosteum and the bone. It was rounded and almost the size of a fœtal head. The space between the tumour and the symphysis pubis would scarcely admit a finger, and this small space contained the rectum and vagina, the bladder being pushed up above the pelvic brim. The tumour consisted of a thick, firm outer portion forming a capsule, within which was contained softer matter of brain-like consistence. A microscopic examination showed the tumour to be a small spindle-celled sarcoma.

Remarks.—There was no possibility of removing the tumour and curing the patient, and next to no chance of her surviving abdominal section; but for the sake of the fœtus, and because of the axiom in midwifery "that no woman should die undelivered," the operation was undertaken. That the patient was delivered of a living child in the natural way fourteen months previously showed extremely rapid growth of the tumour, and it is probably well for the infant, who is strong and healthy, that the mother's condition was not recognised earlier.

Hartlepool

REMARKS ON TWO CASES OF ACUTE BULBAR PARALYSIS.

BY J. P. TILDESLEY, M.B., L.R.C.P.LOND., M.R.C.S.ENG.

THE following description of two cases which have come under my notice is worthy of record on account both of the fact that few uncomplicated cases have hitherto been recorded and also of certain instructive symptoms and pathological conditions which were observed. The patients whose cases I describe were seen in private practice, so that it was possible for me to obtain a post-mortem examination in only one instance.

CASE 1.—A man aged thirty-five had been in fairly good health for twelve months previous to the attack. There was no history of syphilis, nor could I find anything prejudicial in the family history. He had had no previous paralytic symptoms, no muscular atrophy, and no signs indicating relationship to amyotrophic lateral sclerosis, during the course of which diseases the lesion may occur. There was no history of rheumatism and there were no signs of endocarditis. In following his trade he was exposed to cold and damp The attack came on with great suddenness and with no prodromata of any kind, with the exception of slight headache during the day. I saw him an hour after the attack and found paralysis of the lips, tongue, and jaw,

Digitized by Google

and of the arm and leg of opposite sides. The paralysed arm and leg lay quite helpless; the other limbs were unaffected. He could not articulate. He could swallow, but with great difficulty. He had not lost sensation, and his hearing was unimpaired. The pulse was 130 and irregular, and the temperature was 101·4° F. The severity of the symptoms gradually increased; the temperature rose to 104°; swallowing became so difficult that he could scarcely gulp down his saliva, which frequently dribbled from his mouth. It became necessary to inject beef-tea and peptonised milk into the stomach. The attacks of suffocation became more frequent, and death occurred on the third day. At the necropsy a small left-sided hæmorrhage was found in the lower part of the medulla. The position of the hæmorrhage accounted for the "crossed paralysis" present, the lowest pyramidal fibres being destroyed just before the point of decussation, and also the highest decussated fibres on the same side.

CASE 2.—This case, though rapid in its progress, was not so sudden as the above. The patient was a man thirty-nine years of age, and there had been premonitory symptoms for several days previous to the attack. These consisted of headaches, dulness, and slight thickness of articulation of the labials. Paralysis of the limbs soon supervened, and his speech became more entangled and queer, so that he was unable to be understood; swallowing solid or liquid food became alike impossible, only thick foods and soups could be taken, and within ten days from the onset of the symptoms the tongue was apparently completely paralysed, the patient, in order to swallow, having to throw back his head and hold his hand before his mouth in order to prevent the food being pushed out again by the efforts at deglutition. There was no deafness or tinnitus. Motor paralysis of the soft palate was very marked, and in consequence saliva and food were apt to pass into the air passages during attempts to swallow. There was marked facial diplegia, the face being symmetrical but expressionless. Respiratory troubles supervened, with attacks of asphyxia and cyanosis, and the patient died from exhaustion on the twelfth day.

Remarks. — In the above cases, as contrasted with the much more frequent form of progressive paralysis which is due to "pigmental atrophy of the large cells contained in the nerve nuclei of the medulla, associated with circumambient sclerosis," the points to notice are: (1) the suddenness of the attack; (2) the accompanying paralysis of the limbs, due to the lesions not being limited to the motor nerve nuclei; (3) that hæmorrhage, although infrequent in the medulla, appears to be the most common cause of acute bulbar paralysis; (4) that the lesion is more frequent in the lower half of the medulla, affecting primarily the nuclei of the hypoglossal nerve and thus occasioning the difficulty of articulating the linguals, the hypoglossal being the motor nerve to the extrinsic muscles of the tongue and the depressors of the hyoid bone; (5) that the vagus and spinal accessory nuclei are necessarily implicated, the nucleus of the latter nerve being a continuation downwards of that of the former; thus are explained the bronchial expiration and weakened phonation from want of innervation of the muscle of Reissen and the muscles of the larynx. Vomiting, dysphagia, intermittent pulse, glycosuria, and diabetes may also be met with as results of damage to the centres; (6) the motor paralysis of the palate and uvula is accounted for by the fact that the cells of origin of the motor branch of the fifth nerve descend in the medulla as low as the tubercle of Rolando and are necessarily damaged; and (7) a fact noted by Duchenne which I observed in the latter of the two cases described above—viz., that when the tongue was raised with my fingers the patient could depress it forcibly, thus proving that the "depressors of the tongue were not all paralysed."

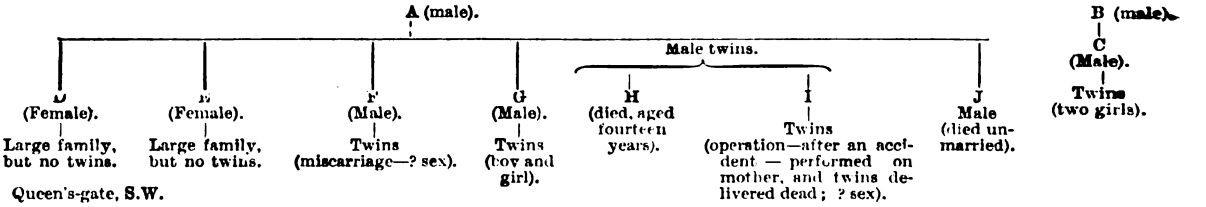
Willenhall, Staffs.

A CASE OF DISLOCATION BACKWARDS OF THE PENIS.

BY L. G. FISCHER, M.B., C.M. EDIN.,
SURGEON-CAPTAIN, INDIAN MEDICAL SERVICE; CIVIL SURGEON, MORADABAD, NORTH-WESTERN PROVINCES, INDIA.

I HAVE ventured to publish this case because, as far as I can discover, it is the only one on record, and I have been obliged to give it the above somewhat extraordinary title for lack of a better term to describe it. A Mahomedan child aged five years was brought to hospital in March, 1895, suffering from infiltration of urine, the result of a fall under a cart sustained four days previously. He was seen at this time by my assistant surgeon, Dr. Jwala Pershad. The perineum, scrotum, and lower part of the abdomen were distended with urine, and gangrene was threatening. Cock's operation was at once performed, and the scrotum, &c., were incised in various directions. Little notice at this time was taken of the state of the penis, which appeared to be normal. The case improved; a fistulous opening formed above and to the left of the pubes, from which the urine passed, and the parents of the child, becoming tired of prolonged treatment, as so often happens, removed him from the hospital. On Aug. 21st he was again brought to hospital, when I saw him for the first time. At first sight the penis appeared to be normal, though shrivelled; it allowed the passage of a catheter for a certain distance, but attempts to pass the instrument into the bladder failed. The urine came from a small opening above and to the left of the pubes in a *full jet* towards the left shoulder, and the extraordinary point, which was at once noticed, was that it could be stopped and expelled at will. The patient was placed under chloroform, and, after various attempts had been made to pass the catheter through the penis, and then through the fistulous opening, into the bladder, without success, I introduced a director into the fistula and slit it up to an extent of some two inches and a half. The glans penis then came into view at the lower end of the incision and at the base of the apparent penis, which was seen to consist of the mere outer covering of the organ. A catheter was now passed without difficulty through the glans into the bladder, and Fig. 1, from a photograph taken at the time with the patient on the operating-table, shows very fairly the condition of affairs. I now carefully dissected out the glans and corpora, which had become firmly fixed in their present position, drew them well forward, and, slitting up the "skin" penis along the dorsum, and paring the end of the prepuce, brought it together round the corpora and fixed it in position with horsehair stitches. The fistulous opening and incision were then closed accurately with horsehair stitches, and dry dressings were applied. Healing went on uninterruptedly, with the exception of slight suppuration in the upper wound, and urine was passed naturally from the penis on the day after the operation. On Sept. 1st, when the wound was nearly healed, the parents were permitted to take the child home. On Sept. 5th they brought him again to hospital, when Fig. 2 was taken, which shows clearly the result of the operation—viz., a perfectly useful organ. There can be no doubt that the penis must have been in some way severely wrenched at the time of the fall, and either the skin and prepuce were caught by the cart under which the boy fell and pulled violently forwards, or the corpora and glans were in some manner violently torn back out of their covering. The result, of course, was extravasation of urine into the surrounding tissues, treated successfully in the first instance by Dr. Jwala Pershad, who may be pardoned for not discovering the real nature of so extraordinary an accident at the time.

Moradabad.



THE INFLUENCE OF INHERITANCE ON THE TENDENCY TO HAVE TWINS.

BY THOMAS WAKLEY, JUN., L.R.C.P. LOND.

THE statistics with reference to the birth of twins, published by Dr. Cory under the above heading in THE LANCET of Nov. 2nd, lead me to think that a rather remarkable history of twin births which has recently come to my knowledge is worthy of being placed on record. The accompanying table would seem to afford very strong presumptive evidence of the hereditary influence of the male members of a particular family with regard to the birth of twins. Unfortunately I have not been able to trace back the family history beyond the brothers "A" and "B." It will be noticed that "B" had but one child, a male, whose wife bore twins—two girls. "A," on the contrary, had a fairly large family, the two female members of which, although bearing many children, had no twins; whilst as regards the five males (two of whom were themselves twins) there is a history of twins among the offspring of three of them, the other two having had no opportunity of showing of what they were capable in respect to this peculiar procreative

Digitized by Google

predisposition. Although I have not been able to ascertain the family histories of the wives, it is obviously very improbable that four women, not related to each other, had also in their respective families a tendency to the development of twins. There is one other point which is, I think, worthy of attention. Dr. Cory says: "When the inheritance comes from the father's side the twins seem to be always of the same sex, so far as the present observations go. This is interesting, for it is generally known that when the twins are joined together they are always of the same sex, and we may, therefore, reasonably suppose that this result is brought about by some abnormal potentiality of the spermatozoa—that is, this form of abnormality comes from the paternal side." It will be seen, however, from the table that, notwithstanding the striking evidence of the inheritance coming from the father's side, "G's" twins were not of the same sex, but a boy and a girl (both of whom, by the way, are living and healthy). I may add that the facts have been communicated to me by "G," of whose intelligence and veracity I have the highest opinion. Knowing that he had twin children, and being interested in the question as to whether the male or the female parent was usually responsible for the abnormality of twin births, I inquired into his family history. It proved to be sufficiently noteworthy, especially in connexion with Dr. Cory's observations, to deserve record.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

LONDON HOSPITAL.

THREE CASES ILLUSTRATING THE MORE SEVERE COMPLICATIONS OF MIDDLE-EAR DISEASE; REMARKS.

(Under the care of Mr. C. W. MANSELL MOULLIN.)

THE publication of cases such as the following, which show the results of operation for conditions which have only of recent years been quite understood, is of great importance. The few that reach our hospitals enter as emergencies, and the necessary operation is performed as soon as possible; therefore they are not brought under the direct notice of any large number of students. The fact that pyæmia due to ear disease may be cured is hardly grasped as yet by many of those who are called upon to see these cases for the first time in private. Only too often patients are sent for hospital treatment when they are almost past surgical help, being nearly exhausted by repeated rigors, high fever, loss of sleep, &c. Quite lately we saw such a case. The girl had been under daily observation at home for a fortnight, suffering from nearly all the symptoms of a septic thrombus in the lateral sinus. Early operation would have saved her life—it was now unsuccessful. Cases 2 and 3 show the mode of onset of the disease, but in each of them some of the more usual and important symptoms were wanting; there were no swelling or tenderness over the upper part of the neck along the internal jugular vein, no swelling of the glands, and no marked tenderness over the mastoid foramen. There is, however, one symptom to which we draw attention as very rare, and that is the external strabismus in Case 2; its occurrence is worth remembering, as its presence in an obscure case of inflammation of the cerebral meninges is rightly regarded as pointing to tubercle as the cause of the symptoms. The site of the thrombus in Case 3 was unusual, and we refer our readers to Mr. Moullin's remarks on the case.

CASE 1.—A boy fourteen years of age was admitted into the London Hospital on May 18th, 1894, in a semi-comatose condition. For about seven years he had had a discharge from the right ear. There was no history of pain or of earache, but he was almost deaf on that side. Three weeks before admission the right temporal region became swollen and tender; at the same time he began to suffer from severe attacks of pain in the right ear and eye. There was no history of injury. He had been sick and delirious, but was said not to have had any shivering fits. On admission he lay upon his left side with his arms and legs drawn up and his hands protecting his face from the light. He was only partially conscious and seemed to be in great pain, frequently uttering shrill cries. The right temporal region was swollen, œdematous, and excessively tender. The temperature was 102° F. and the pulse and respiration both much hurried. There was no optic neuritis. Two hours after admission the patient was anæsthetised and an incision two inches in length made over the temporal region a little below the temporal ridge. The temporal muscle was sodden and acutely inflamed, a large amount of bloodstained serous fluid escaping from it as soon as it was incised; and the same was the case with regard to the periosteum, which was partially detached from the bone beneath, but no pus was found. The incision was then carried backwards over the ear on to the mastoid process, and a circle of bone was removed with the trephine from over the lateral sinus. As this was found not to be affected, and as there was no evidence of increased intracranial tension or of suppuration between the dura mater and the bone, the circle that had been removed was replaced and the posterior part of the incision carefully sutured. The anterior part was drained and dressed separately. The next day the temperature began to fall, and the boy regained consciousness. Two days afterwards he was almost free from pain and perfectly rational, and the temperature was normal. The posterior part of the wound had healed, but there was still an offensive discharge from the ear in spite of frequent syringing. A fortnight later the squamous portion of the temporal bone, where the periosteum had been incised, was still bare, and there was a small collection of pus in the temporal fossa, causing a rise of temperature for a day or two. At the end of the month the bone was completely covered in; the wound had healed except a small button of granulations, and the boy was discharged.

CASE 2.—A young man nineteen years of age was admitted into the London Hospital on Sept. 19th, 1895, with pyæmia consecutive to an attack of acute otitis media. There had never been chronic otorrhœa. His illness had commenced suddenly sixteen days before with violent pain in the right ear and head. There was no facial paralysis, no swelling or tenderness over the mastoid, and no pain on percussing the bones of the head. The membrana tympani had been recently perforated, and on syringing the meatus a good deal of stringy, bloodstained pus was washed out. The pupils were normal; there was no optic neuritis. The temperature on admission was 104° F., and there was a history of several rigors having occurred already. The next two or three days the temperature remained exceedingly irregular, rising on two occasions to 106°. There was no headache or drowsiness, but a certain amount of stiffness was complained of in the muscles at the back of the neck. Then paralysis of the external rectus of the opposite eye suddenly made its appearance. The left shoulder, too, became painful and seemed to be slightly swollen. As the pyæmic symptoms were becoming more and more marked, in spite of the free discharge from the ear, the patient was anæsthetised and a circular disc of bone removed with the trephine from over the lateral sinus. On

Digitized by Google

exploring this it was found to be plugged with clot. There was no pus or sign of inflammation on the outer surface of the dura mater. The bone on either side of the trephine opening was cut away with Hoffmann's forceps, the sinus laid open, and the softened clot cleared out until the blood flowed freely. The jugular vein was then exposed in the neck and tied; it was not thrombosed. The same evening the patient had a rigor, the temperature rising to 105·2°, and the next morning the shoulder was much more swollen. Two days afterwards two rigors occurred, and then for the next four days one daily, gradually diminishing in severity. The last sudden rise of temperature (without shivering) was on the fourteenth day after operation. In spite of the rigors, however, the patient's appearance began to improve at once; the pulse became stronger and slower, he slept better, and the wounds healed well. The swelling of the left shoulder disappeared, and at the time of his discharge, five weeks later, the left external rectus had almost regained its power.

CASE 3.—A man thirty-one years of age was admitted into the London Hospital on June 5th, 1895. There was a history of otitis media with discharge from the right external meatus and partial deafness for some years. A week before admission he had received a blow upon the ear. This was followed by swelling over the mastoid, intense pain shooting into the temporal region, cessation of the discharge, high fever, and general drowsiness. There was no paralysis; the pupils were normal, and there was no optic neuritis. A rigor occurred the day after admission; it was uncertain whether there had been one before. The ear was syringed out, and the next day, as the symptoms did not subside and the drowsiness was deepening into partial coma, an incision was made over the mastoid process, and the mastoid antrum and cells thoroughly cleared out. A small quantity of pus was found under the periosteum and in the bone, but none on the inner surface under the dura mater. The lateral sinus was laid bare a little further back, through a separate trephine opening, and incised freely. There was no evidence of thrombosis, so the wound was plugged with iodoform gauze to stop the bleeding. The jugular vein was also exposed in the neck, but appeared to be perfectly free. The temperature, which was 103·2° F. at the time of the operation, fell the same night, but the relief was of very short duration. A rigor occurred the next day and at frequent intervals afterwards. The patient's condition rapidly went from bad to worse. Pleurisy and pericarditis set in, and death ensued eight days after admission. At the post-mortem examination there was abundant evidence of pyæmia. The emboli had started from the lateral sinus, which was filled with softened and partially decolourised clot beyond the spot where it had been opened, nearer to the middle line. As the lateral sinus on the right side was plugged with gauze the emboli must have been detached at the torcular and carried down the opposite jugular vein. The clot had, in all probability, been present at the time of the operation, and the blood which flowed freely when the sinus was opened had regurgitated from the jugular vein and the smaller sinuses.

Remarks by Mr. MANSELL MOULLIN.—These cases are good examples of the results that follow neglected otitis media, and form a striking illustration of the value of the treatment described by Ballance.[1] In the first case the infection spread forwards; there was acute inflammation of the temporal muscle and of the squamous portion of the temporal bone, limited, fortunately, to the external surface. The cerebral symptoms were very suggestive of intra-cranial suppuration; but as they subsided as soon as the pericranium was incised and the bone trephined they were probably caused by increased tension and hyperæmia, like those that occur in diffuse cellulitis of the scalp. It is noteworthy that the nutrition of the circle of bone removed with the trephine was not in any way impaired. It had united firmly in its place some time before the boy was discharged. In the second case the pyæmic symptoms, as in several cases previously recorded, were already marked; but apart from the knowledge of what must have been going on in the ear, the only evidence of local thrombosis was the stiffness in the muscles at the back of the neck, and even this was only complained of after inquiry. There was no tenderness, œdema, or swelling over the mastoid. The infection must have spread directly to the sinus, along the veins, without implicating the bone or the extra-dural lymphatic spaces. The paralysis of the external rectus of the opposite eye, which developed one day suddenly and painlessly, may have been due to some secondary pyæmic affection or to direct extension of inflammation along the dura mater. There was no evidence one way or the other. In the third case, which unhappily terminated fatally, there can be little doubt but that the septic infection spread between the dura mater and the bone until it involved the wall of the lateral sinus and led to thrombosis. The actual path taken could not, however, be made out. It is clear that it did not involve the nearest part of the sinus, for this was laid open and was perfectly free. In some way it must have missed this and reached the wall beyond; for the part that extended towards the torcular was filled with offensive, softened débris. Had the operation been carried further and a much larger portion of bone removed, it is possible that the result would have been different. Then the condition of the sinus could hardly have escaped observation; but there was no indication in the symptoms that pointed to this.

[1] THE LANCET, May 17th and 24th, 1890.

WESTMINSTER HOSPITAL.

SECONDARY SUTURE OF THE PATELLA, WITH RESECTION OF THE QUADRICEPS EXTENSOR TENDON.

(Under the care of Mr. WALTER G. SPENCER.)

THIS case serves to emphasise the importance of suturing the patella in suitable cases as soon after the accident as possible and not leaving it until the extensor muscles are shortened and contracted, and the separated upper fragment adherent. The difficulties of secondary suture are often considerable and the contraction of the extensor tendon very difficult to overcome. In similar cases where the upper fragment has not been adherent, this shortening of the muscles has been remedied before operation by tenotomy, or by gradual extension after the fixation of a wire to the upper fragment. The exact method of division of the quadriceps extensor when the operation is completed at one sitting varies somewhat; the one adopted by Mr. Spencer was very successful.

A soldier was thrown at football and injured his knee. He was treated in bed for a month, lotions being applied, and six weeks after the accident was discharged from the army, his limb being useless. Seven months after the accident he came under Mr. Spencer's care. The upper fragment of the patella was firmly fixed to the femur between five and six inches above the lower fragment, the space between being filled with softish masses. The quadriceps extensor muscle was much wasted, as were also to a less extent all the other muscles. The most striking feature was the complete want of power in the whole lower limb. He could only swing it by the action of the psoas and iliacus. The quadriceps extensor had been put out of action and the antagonistic flexors were equally powerless as in complete wrist-drop, so that the knee-joint was rendered loose and no weight could be put on the limb without it bending. After the application of an elastic band above, a rectangular flap was turned *downwards* and the wound further enlarged by a vertical incision upwards from the outer and upper angle in order to reach the upper fragment. A brownish-yellow fatty mass of organised blood clot filled the joint and had to be removed first of all as in arthrectomy. No connexion between the fractured ends even of a membranous nature was met with. The fractured surfaces were refreshed, and the upper fragment was separated from its connexion with the femur. But no approximation of the fragments could be obtained even when the thigh had been flexed to a right angle with the trunk with the knee fully extended. The quadriceps extensor tendon was, therefore, resected as follows. The aponeurosis of the tensor fasciæ femoris and that of the external vastus were divided, muscle fibres only being left; the rectus tendon was advanced by dividing it obliquely upwards and backwards, so that elongation was obtained without any actual gap; finally, the thin aponeurosis of the internal vastus had to be cut through. Two strong pieces of silver wire having been looped round the two fragments antero-posteriorly, as in Mr. Barker's plan for primary suture, and with the use of considerable force, the fragments were brought well together. The remaining muscular portion of the quadriceps extensor stretched sufficiently as the limb was held flexed to a right angle with the trunk. It was only after some days that gradual extension at the hip was allowed.

Digitized by Google

The elastic band was not removed until after the application of the bandage. Healing took place with sound bony union. There was some oozing of blood, occasioned, no doubt, by the removal of the masses of organised blood clot, and the edge of the flap at its upper and inner angle sloughed a little from want of sufficient blood. The faradaic current and massage were used for the wasted muscles.

Remarks by Mr. SPENCER.—Eight months after the accident the man had a strong leg free from all pain. He is at work and can go upstairs easily. He can move his knee-joint a little, but I have not yet encouraged him to do so, for the quadriceps extensor is still shrunken. Although, therefore, this case is thoroughly satisfactory as one of secondary suture, yet it falls short of what might have been obtained by the very much less severe operation of primary suture.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Cystic Accessory Thyroid.—Classification of Sarcomatous Tumours of the Bladder.—Macrodactyly due to Diffuse Lipoma.—Acute Tuberculosis of Spleen.—Hydronephrosis from Malignant Disease of Ureter.—Card Specimen.

AN ordinary meeting of this society took place on Nov. 19th, the President, Mr. BUTLIN, being in the chair.

Mr. EDMUNDS described a specimen of Cystic Accessory Thyroid. The tumour was of a globular shape between 4 and 5 cm. in diameter. It consisted of one large cyst; in the cyst wall on one side was a solid substance about the size of an almond. The cyst contained a pale-brown glairy fluid. Into the cavity of the cyst there projected two vegetations, the smaller of which was removed for examination. Microscopic examination of the solid substance showed it to resemble thyroid tissue; it consisted mainly of vesicles, some of which contained colloid secretion; it differed, however, from normal thyroid in (1) the existence between the vesicles of a considerable amount of lymphoid tissue consisting of small deeply-staining cells embedded in a fibrillar network containing bloodvessels, and (2) in the majority of the vesicles containing no colloid, but being wholly occupied by large cells formed by the multiplication of the secreting cells lining the vesicles. Examination of the vegetation showed it to consist internally of a coarse fibrous tissue, externally to that of a layer of fibrous tissue and again external, and constituting the lining of the cyst of a layer consisting of large thyroid secreting cells, among which was some colloid secretion. The tumour was removed during life from below the angle of the jaw and was not connected with the thyroid body, which seemed normal. The patient was a man aged twenty-eight who had noticed the growth some months.—Mr. BERRY remarked that most of the cases which had been described under this heading could be divided into one of three classes. 1. True masses of thyroid tissue distinct from the main gland; these were extremely rare. 2. Tumours connected with the main gland more or less definitely by pedicles or prolongations of capsule; these, as a rule, lay either above the gland in the line of the lingual duct or at the upper or lower end of the lateral lobe; they were frequently found post mortem. 3. Tumours originating in the normal gland, which, as they grew, stretched the capsule and became separated from the gland. He showed the photograph of a tumour which was situated near the angle of the jaw, and at the operation for its removal the thyroid gland was not distinctly seen. A post-mortem examination was performed on the same case shortly afterwards, and it was then found that the tumour had been directly continuous with the upper part of the lateral lobe of the thyroid gland.—Mr. TARGETT said there was one large specimen in the museum of the Royal College of Surgeons of England where the tumour, which was as big as a lemon, pressed on the bronchus. The tumour in parts was dense and contained calcareous matter and cysts.—Mr. BARKER asked if there was any difference in the microscopical characters of the three varieties Mr. Berry had described.—Mr. BERRY said that practically the structure was the same in all.—The PRESIDENT added that often at an operation no obvious connexion was seen between the tumour and the thyroid gland, and surgeons would not as a rule feel inclined to search for such connexion.—Mr. EDMUNDS briefly replied.

Mr. TARGETT read a paper on the Classification of Sarcomatous Tumours connected with the Bladder, and illustrated his remarks by numerous specimens, microscopic sections, and lantern plates. He said that during the past few years the subject of sarcomata of the bladder had been ably dealt with by Messrs. Southam, Fenwick, and Barling. The classification of the vesical tumours proposed by the last-mentioned writer was compared with that given by the text-books of surgery and pathology in present use. Exception was taken to the use of the terms mucous and fibrous polypus in respect of bladder growths, and many preparations were shown illustrating the chief anatomical and histological differences in the polypoid formations of the bladder. It was proposed to adopt in the main a clinical classification of the growths variously styled fibro-myxoma, myxo-sarcoma, myo-sarcoma, &c., grouping them all under the head of sarcomata, and then arranging them as those belonging to childhood and those belonging to middle age onwards. These two groups were then subdivided by anatomical considerations as to the primary seat of the disease, and examples of each subdivision were exhibited and described. In conclusion the malignancy of the growths occurring in childhood was discussed from a clinical and pathological standpoint.—Mr. HURRY FENWICK claimed to have pointed out that the so-called myxomata of children were not really myxomata but sarcomata. They often looked like nasal polypi, and this was due to a gelatinous translucency of their surface caused by the pressure of the growth upon the venous circulation of the bladder. A true myxoma in the adult was to be found in the Leipsig Museum.—Mr. SHATTOCK defended the term "mucous polypus" as a name for some of these bladder growths in children. They resembled precisely the mucous polypus of the nose; there was no invasion of the muscular tissue, no metastases, and Virchow had shown that in some parts they were often distinctly cellular. In the nose the diffuse form was represented by the hypertrophy of the mucosa of the middle turbinated bone.—Mr. D'ARCY POWER held that in discussions upon growths of this kind the whole of the genito-urinary tract should be considered together. The specimen which he had recently shown as affecting the vagina was almost identical with some of the bladder growths exhibited; they agreed also in their polypoid shape, with surface œdema, in the absence of metastasis, and in the rarity of gland infection. He asked whether the chondro-sarcoma of the bladder which had been shown was a primary or a secondary growth.—Dr. SNOW said that the pathological classification of these growths at the present time was one of distinction without difference and might with advantage be much curtailed. A so-called "polypus" might be produced by the mechanical detachment of a small piece of mucous membrane, the submucous tissue of which afterwards underwent thickening. Nearly all the tumours of the bladder tended ultimately to become polypoid, and papilloma was commonly only a stage of early malignant growth.—Mr. TARGETT, in reply, said that in the specimen of chondro-sarcoma the secondary mass noticed was in the glands and only appeared after the primary growth had been long in existence. Some of the myxomata of the bladder were mucoid degenerations of sarcomatous growths.

Mr. D'ARCY POWER showed a case of Macrodactyly due to Diffuse Lipoma. The child was originally under the care of Dr. Hugh Jones of Dolgelly, and the specimen was shown for Mr. Robert Jones of Liverpool. It consisted of the greatly enlarged right thumb and index-finger of a girl aged eighteen months. The thumb was widely abducted and its ungual phalanx was hyper-extended. The forefinger and the hand were deflected to the ulnar side. The nails of the two enlarged digits were normal. The swelling was noticed at birth, and it increased slowly until the hand became useless. The enlargement involved the thenar side of the hand upon its dorsal as well as upon its palmar aspect. The skin over the affected parts was a little redder than upon the sound side, but it was smooth, soft, elastic, and not lobulated. Amputation of the thumb and index-finger was performed by Mr. Robert Jones, and the child now had a useful hand. Subsequent examination showed that the swelling was due to an overgrowth of the normal subcutaneous adipose tissue. The blood-supply was not increased, and there did not seem to be any change in the lymphatics of the part. The adipose tissue had infiltrated the voluntary muscle, and it was more abundant upon the flexor than upon the extensor aspect.—Mr. POWER, in commenting upon the case, said that it was

Digitized by Google

one of true macrodactyly, and that it agreed with the majority of the cases recorded in the fact that it occurred sporadically in the family, that it was unilateral, and that it did not affect all the digits. It differed in the fact that it was truly congenital, whereas in most cases the enlargement was only noticed some time after birth. He then called attention to the likelihood of assuming that such enlargements were of lymphatic origin, and he urged that they should be treated more actively, for they consisted of a surely if slowly growing form of connective tissue.

Mr. MARRIOTT described a case of Acute Tuberculosis of the Spleen in which splenectomy was followed by recovery. The patient was a woman aged thirty in whom an abdominal tumour had been noticed two years previously. There was neither history nor sign of syphilis, nor were the lymph glands enlarged. The tumour steadily increased in size and caused no pain; latterly, as it enlarged more rapidly and as the diagnosis was doubtful, an exploratory abdominal section was performed, and an enlarged spleen was removed. The patient made a good recovery and was in good health eight months after the operation. The spleen was uniformly enlarged, measuring 8 in. long, 5 in. from side to side, and 3 in. in thickness. The natural outline of the organ was preserved, but the convex aspect of the spleen was studded with coarse, round nodules, closely resembling a hob-nailed liver. On section the spleen pulp was stuffed with yellowish-white, slightly raised deposits. Microscopically these contained numerous grey tubercles, clustered for the most part, thus explaining the nodules above described. There was very little caseation. A chronic vulvar ulcer which had been excised was looked upon as the source of infection, but there was no clinical evidence of any other organ than the spleen being infected.—Dr. COUPLAND remarked on the extraordinary size of the spleen for a case of tuberculosis. He inquired if there was evidence of tubercle elsewhere.—Mr. TARGETT replied in the negative.

Dr. RUNDLE showed a specimen of Hydronephrosis due to Malignant Disease of the Ureter. The patient was a man aged forty-six, who was admitted into the Royal Portsmouth Hospital in April, 1895, with a history of a swelling in the abdomen of a year's duration. This was diagnosed as hydronephrosis connected with malignant disease of the bladder. Post-mortem examination showed that the disease probably started at the vesical end of the right ureter and spread upwards along the ureter, below into the wall of the bladder, and laterally into both vesiculæ seminales. The secreting portion of the kidney, as a result of the obstruction, became first dilated and afterwards destroyed, and the kidney converted into a series of sacs.

Dr. WALSHAM showed, as a card specimen, Meckel's Diverticulum with an attachment to the Mesentery.

OPHTHALMOLOGICAL SOCIETY.

Three Cases of Exophthalmic Goitre with Severe Ocular Lesions.—The Treatment of Detached Retina.

AN ordinary meeting of this society was held on Nov. 14th, Mr. EDWARD NETTLESHIP, President, being in the chair.

Mr. JESSOP read an account of Three Cases of Exophthalmic Goitre with Severe Ocular Lesions. Case 1: A married woman aged forty had extreme proptosis of both eyes; she had never been pregnant and had always menstruated irregularly; there was no enlarged thyroid. The operation of partial tarsorhaphy was performed on both eyes. Four days afterwards swelling of the right conjunctiva developed, followed by crescentic ulcer of the cornea and chemosis of the left eye. Both eyes then ulcerated, and the corneæ necrosed, notwithstanding active treatment. The corneæ were reduced to Descemet's membrane and perforated. At present there were staphyloma of both corneæ and extreme swelling of the conjunctivæ. The patient is still alive, but very weak. Case 2: A woman aged thirty-five, under the care of Mr. Power, with extreme proptosis of both eyes; both corneæ sloughed. The right eye was excised. The patient became insane and died. Case 3: A woman aged twenty-four, under the care of Mr. Vernon, with extreme proptosis; the right eye sloughed and was excised; in the left eye there were recurrent attacks of superficial corneal ulceration. Reference was made to 25 recorded cases, 7 males and 18 females. The results in the 7 males were more severe and included 4 deaths; the ages were between thirty-eight and fifty-six. Of the 18 females 2 died and 10 lost both eyes; the ages were between eighteen and fifty-two. The results of 3 cases of partial tarsorhaphy in women were that 2 lost both eyes and 1 recovered with good vision, though there was superficial corneal ulceration.—Dr. LITTLE said he had never seen any case bad enough to require suture of the lids. The eye had been removed in Mr. Power's case on account of continued pain and discomfort, which he thought might have been due to something behind the eye. The ulceration, he thought, was not necessarily caused by exposure, as it was not an uncommon thing to see no ulceration in eyes which were never closed even in sleep.—Dr. MCKENZIE DAVIDSON described a case under his care in which both corneæ sloughed; the patient became insane, but afterwards recovered. In another case he performed tarsorhaphy, and the corneæ were preserved. In a third case the surface of the cornea was entirely destroyed.—Mr. LANG said he had performed the operation in one case, but the stitches gave way and the cornea perished. The stitches did no harm.—Mr. JOHNSON TAYLOR was of opinion that the suturing should be complete and not partial, and should be carried out as soon as the cornea showed signs of injury.—Mr. LAWFORD recorded one case in which there were great proptosis and ulceration of the cornea. The lids were sutured in the centre instead of at the canthi, and the result was very good. The union of the lids was a great safeguard.—The PRESIDENT recorded five cases of damage to the cornea in Graves' disease. He was in favour of suturing the lids firmly with wire sutures. Bad results followed imperfect attachment. In one case, a man aged fifty-two with extreme proptosis and ulceration of one cornea, a good result followed suturing. All cases were intolerant of lotions or bandaging.—Mr. JESSOP, in reply, asked that all cases might be put on record, as very few had been hitherto reported.

Mr. WRAY read a paper on the Treatment of Detached Retina. The results of treatment in a case in which the distorted vision began in 1885 were demonstrated. The patient was seen for the first time in January, 1893. The left eye had barely perception of light, and the right eye contained a large detached retina involving about half of the fundus. The tension was decidedly raised, but the patient was, and had been, quite free from pain. As the other eye was quite blind from a penetrating wound, and had been so for many years, it was removed in the interest of the good eye. No more was seen of the case until January, 1895. The eye, under ophthalmoscopic examination, was found to contain a very large detachment, considerably larger than on the occasion of the last visit; so large, in fact, that although the media were clear it was almost impossible to obtain a view of the disc. The tension was still markedly raised and the cornea slightly hazy. Vision was reduced to perceiving hand movements at a distance of from four to six inches. The case was subsequently exhibited at the Ophthalmological Society. On April 7th the patient was operated on by tapping the detachment and a quantity of dark-yellowish fluid evacuated. He was then put to bed, atropine was freely used, and the eye firmly bandaged. Daily injections of pilocarpin were ordered, but had to be discontinued on the third day on account of the patient's intolerance of the drug. A week later ophthalmoscopic examination showed there still existed a detachment of very considerable size, though the vision was improved to seeing fingers three or four metres distant. After allowing a few days for the patient to recuperate, a second operation was done, with the result that vision improved to $\frac{6}{24}$ in a good light, and the sight had fluctuated between that and $\frac{6}{36}$ ever since. The retina now appears in perfect apposition, and there exists, as is usual in such cases, a certain amount of choroido-retinal atrophy, with pigmentation at the seat of the original detachment. The fields are much contracted, doubtless from the tension. The case proves that good may result from operative treatment even in very severe cases of several years' duration. Little was to be expected from pilocarpin, and especially in elderly people and those suffering from cardiac disease. As the perfect rest, treatment with atropine and bandage entailed confinement to bed for at least three or four weeks under almost insupportable conditions, and with the prospect of almost inevitable failure, it would seem better to operate at once, especially as the operation is almost free from risk under proper surgical precautions, and most surgeons do eventually operate after the failure of the simple treatment. As regards recent cases speedy reattachment was necessary to prevent loss of function. If the sub-retinal fluid existed in any amount several weeks would be required to obtain absorption and reapposition, whereas anatomical union was desirable, and

Digitized by Google

probably the absence of this latter explains many relapses. In chronic cases there will be even less tendency to rapid absorption, and therefore it would seem reasonable to tap at once, so that the period of confinement to bed is spent in promoting an actual adhesion of the retina to the choroid. Cases unsuitable for operation are those where the macula is detached, where the vitreous contains numerous bands of contractile tissue, vascular membranes, large hæmorrhages, &c., and where the detachment is almost total, or the tension of the eye as low as – 3. A good result has been published in which the operation was done in a recent case with tension – 2. Clavelier's experiments proved that currents of five milliampères could be used for a minute without causing anything beyond transient opacity of the vitreous, and one operator had published eleven cases in which he used electrolysis and obtained three ameliorations and two cures. As such currents cause only a transient opacity of the vitreous and leave no ophthalmoscopic changes behind, it is just possible that the beneficial results after electrolysis were due to leakage around the positive pole during the protracted period the needle was *in situ*. Constitutional remedies directed against gout, rheumatism, syphilis, &c., are slow in their action, usually depressing, and after long trial have not yielded results to warrant persistence in their use as therapeutic agents for an emergency, but should undoubtedly be used later.—Mr. DEVEREUX MARSHALL did not think it probable that tapping the detachment would assist the diagnosis by examination of the fluid evacuated in the case of tumour, as this would not be broken up by tapping.—Mr. JESSOP stated that in his experience the detachment returned or became worse after tapping. He had one case in which the retina had become restored to its place after treatment by rest and pilocarpin; considerable pigmentation occurred in the re-attached area.—Dr. LITTLE had had two cases in which complete permanent cure was effected, and he had seen no recoveries without.—Mr. SECKER WALKER recommended the injection of normal saline solution into the vitreous after withdrawal of the fluid from the detached area. In one case a temporary glaucoma had ensued, but the retina remained attached five weeks.—Mr. LANG cited two cases of cure under simple treatment by rest. He had tried puncture in various ways without success.—Mr. TWEEDY had operated by every possible method, but had never seen a permanent cure—only some improvement. He doubted the diagnosis in cases of cure. Scleral puncture he considered right. In one case of a myopic patient, vision which had been reduced to perception of hand movements was restored to J. 1 with rest and pilocarpin, and the improvement lasted some time.—The PRESIDENT was able to give the further history of the case; he had seen her seventeen months later, when she was quite well and there was no sign of detachment.—Mr. POWER cited a suggestion that fresh vitreous from a cat or dog should be injected into the vitreous chamber to replace the retina by pressure.—Mr. JOHNSON TAYLOR asked if any member had used elaterium.—Mr. GRIMSDALE had seen Mr. Frost attempt to inject vitreous, but it had been found impossible to make it flow through a syringe.

HARVEIAN SOCIETY OF LONDON.

Spasmodic Asthma.

A MEETING of this society was held on Nov. 7th, the President, Sir JOHN WILLIAMS, Bart., being in the chair.

Dr. GOODHART read a paper on Spasmodic Asthma. Referring to various opinions as to the pathological changes in this condition, he said his own inclined to the hypothesis of muscular spasm; but, dealing with the cause, there could be no doubt that the disease was a purely nervous phenomenon. As proof of this he adduced the suddenness of onset of the attacks, their association as an early incident in diseases which especially affect the nervous system, such as malaria and influenza, and its alternation with trophoneuroses, such as eczema, urticaria, and psoriasis. Of all these points illustrations were given. Dr. Goodhart then pointed out that the subject was unduly complicated by including such conditions as hay fever and the asthma of bronchitis. He thought, however, that paroxysmal sneezing was due to the same form of nervous instability. Allied to both were other neuroses, of which he instanced Raynaud's disease and the gastro-pulmonary fever of childhood. Asthma, he said, was largely a disease of childhood. This was contrary to the general belief. His own experience and Hyde Salter's statistics showed this; 73 cases out of 121 of the author's cases began before maturity. Turning to the treatment of asthma, Dr. Goodhart believed that the most important thing was to direct their measures to cure the underlying nervous condition, remembering always that they had to deal with a paroxysmal neurosis comparable to epilepsy, migraine, and insanity. It belonged to all of these that the more they came the more they stayed, and the essential indication was to prevent and so break the vicious habit. It should be encountered early—in the child—and by measures of two kinds, whether drugs or other—the one directed to changing the environment, the other to increasing the resistance of the subject. In later life the common practice is to relieve the paroxysm by the inhalation of fumes, and this being done on the patient's own responsibility the malady itself is neglected, while he is left in a worse state than before by the use of his temporary remedy, the lung trouble being increased thereby, and often dilatation of the heart could be ascribed to indulgence in "fumes." The rational treatment of asthma should begin, if possible, with the child. The first thing, and a difficult one, is to find and secure a favourable climate—in any event to oppose the system of coddling and in-door cultivation. A bracing open-air life, reasonable care in diet, and healthy recreation gave the best results. Amongst drugs arsenic was extolled. The treatment of the paroxysm must be guided first by the cause which seemed to induce it; thus, if it followed a meal, an emetic might serve. Iodide of potassium, combined with ethereal tincture of lobelia, seemed to be useful when an attack was impending: when actually in progress a subcutaneous injection of morphia might be given, or the patient made to inhale chloroform. Dr. Goodhart then dealt with the treatment of the asthmatic diathesis in adults, and pointed out the measures to which resort might be had in different cases.

Dr. ILLINGWORTH showed the analogy which existed not only between asthma and epilepsy, but also between it and migraine, angina, and flatulent colic, the symptoms in all being fundamentally similar—collapse, with feeble, fluttering pulse, low temperature, and heavy, dull pain. He grouped these together as venous disorders named the "anginal group." The accepted pathology he regarded as wrong. The symptoms point to venous congestion with consequent effusion of carbonic acid gas into the air cells. Hence the short inspiratory efforts, prolonged expiratory ones, and the relief felt on putting the head low down, allowing this heavy gas to flow out. All these disorders are benefited by nitrites, but especially by belladonna in large and frequent doses. The relief from potassium iodide is from its fluidising effect on the stagnating blood. Antifebrin acts well also in the same way. As stimulants the best effects are got from belladonna, ether, and the nitrites, the former and latter also acting as peripheral vascular dilators. Hay asthma he stated to be rapidly curable by inhalations and douches of warm biniodide of mercury solution of the strength of 1 in 1000.

Mr. PARKER YOUNG congratulated the council on having secured Dr. Goodhart to read a paper on so important a subject, and said the number of members present testified that when they were able to hear such a subject discussed a much larger number attended than usual. He came to the meeting to try to learn if there was any fresh remedy or treatment, as he (like many other members) suffered from the complaint, and out of the remedies suggested he had found that the most efficacious were fumes of saltpetre dissolved in blotting-paper and the inhalation of chloroform. He stated his attacks came on from hurrying, and in going up a hill the attacks of dyspnœa were very severe. Formerly he also found that addressing public meetings, excitement, &c., affected the nervous system, the pneumogastric nerve playing an important part, relief coming from vomiting, sleep, or exciting the mucous membrane of the nasal organs to copious secretion. He thought there was much yet to learn in the disease, and his experience of drugs as suggested by various speakers was not as satisfactory as he could wish. They had been tried by his friend sitting on his right, who was a fellow sufferer, with not very beneficial results.

Dr. EDWARD SQUIRE was disposed to question whether asthma is more particularly a disease of the upper strata of society. As to age, he asked whether the preponderance of children might not be partly explained by the fact that asthmatic children are brought to the medical man in the hope that the disease may be cured before they grow up, whilst

Digitized by Google

the adult asthmatic, despairing of cure and having found some remedy which eases his attack, treats himself with his favourite "fume" or powder. Dr. Squire unhesitatingly expressed his preference for the "fresh air" over the "hot-house" treatment. Undue "coddling" was in his opinion harmful. With regard to localities suitable for asthmatics nothing could be said in general terms; each patient must find out for himself what locality suits him best. Some asthmatics are better in the open country, and some are most free from attacks in the smoky atmosphere of a manufacturing town. A student at University College used, on the onset of an attack, to take a tramcar towards Hampstead, and when a certain distance on the way the attack went off. On the other hand, a child living in the fresher air in the neighbourhood of Hampstead was brought on to the Metropolitan Railway, and in the atmosphere between Baker-street and Gower-street stations the attack passed off. This might be an instance of treatment by "fumes." As to drugs, Dr. Squire had found such satisfactory results from iodide of potassium in large doses (ten grains to twenty grains three times a day) that he generally prescribed this for adults. He had often seen patients who had had frequent attacks before admission keep free from them for the six weeks or more whilst in hospital. The iodide cannot, however, be considered a cure for the disease, as the attacks generally return when the remedy is discontinued. Chloroform inhalation is sometimes useful during an attack, but requires to be used with care. Dr. Squire had seen alarming collapse follow chloroform inhalation during an asthmatic attack. Morphine hypodermically will always give relief. The various "fumes" are undoubtedly useful in many cases. Dr. Squire advocated examination of the nose in asthmatic patients. He had had cases in children where removal of adenoids had cured asthma. He considered the prognosis good in children, but the disease is much more intractable in adults.

Dr. GREVILLE MACDONALD, in remarking on the association of intra-nasal disease with spasmodic asthma, regretted that his experience had perhaps been hardly sufficient to justify his drawing any definite conclusion, and, remembering the views arrived at by some admitted to be authorities, he felt the more diffident in urging the points concerning which he wished to make a few remarks. Of thirty cases of nose disease associated with asthma he had had twenty manifestly relieved by local treatment, while of these twelve might be quoted as tantamount to complete cures. Of the twenty, four were cases of obstruction due to septal deformities, six were of vascular engorgement or hypertrophy of the inferior turbinated bodies, four were of polypus, and four of adenoids, while the remaining two were instances of that curious œdematous swelling over the upper and anterior portion of the triangular cartilage so often associated with paroxysmal sneezing. The remaining ten cases unrelieved were all due to polypus. He believed that the latter condition was more often associated with chronic bronchitis than with simple spasmodic asthma, and must be considered as a concomitant of rather than as responsible for the bronchial symptoms. From these cases he purposely excluded hay asthma, for he regretted to have to confess that he had but seldom found this symptom relieved by intra-nasal operation, although, so far as the more severe symptom—the sneezing—was concerned, he was greatly encouraged by the results of treatment. Dr. MacDonald then gave particulars of three cases of complete relief of severe spasmodic asthma which had been treated by himself, the results of operation being so immediate and so emphatic that there could be no doubt that the *post hoc* was *propter hoc*. He believed that spasmodic asthma, together with paroxysmal sneezing, was more frequently seen in the out-patient departments than ten years ago, and that they could no longer be considered as among the privileges of the upper classes. Possibly the fact was to be explained by the increasing excellence of primary education or on the supposition that the upper classes were more commonly frequenting the hospitals.

EPIDEMIOLOGICAL SOCIETY.

Return Cases of Scarlet Fever.

A MEETING of this society was held on Nov. 15th, Mr. SHIRLEY F. MURPHY, President, being in the chair.

Mr. T. W. THOMPSON, medical inspector of the Local Government Board, read a paper on Return Cases of Scarlet Fever, or those appearing in a family so soon after the return home of a convalescent from the hospital as to be deemed the result of infection from the returned patient. We print this paper in full on pp. 1277–81 of our present issue. Mr. Thompson said that 3 per cent. on the total admissions was a probable average of such cases, and the public assumed negligence on the part of the medical officers and hospital authorities and premature discharge of the patient, while they in their turn were inclined to find an explanation rather in independent sources of infection—as schools, imperfect disinfection by the sanitary authority, or the evasion of the process in the case of clothing. The class of house seemed to have more influence than any other single factor, pointing rather to the surroundings and thoroughness with which home precautions were carried out. Cases occurring after the patient had been quarantined for a fortnight in a pure air were due to the fact that we could not say when each individual ceased to be infective.

Dr. GOODALL considered the inquiry one for medical officers of health, since a large number of return cases from being taken to other hospitals were not recognised as such. Many patients were infectious after desquamation and all visible catarrhs had ceased. He related the case of a child who was admitted from the workhouse owing to a subsequent attack of measles, and after being detained in hospital for six months conveyed infection to the relatives to whom she went on her discharge, with not a garment or toy from her former home. At the same time disinfection, even by the sanitary authorities, was not always satisfactory, people constantly secreted their best clothes, &c., lest they should be spoiled, so that secondary cases, not returns, frequently followed after a week to a month without any communication with the hospital. It must, however, be remembered that we could not disinfect a person as we could a garment; nature only could eliminate the poison in course of time.

Dr. PARKES asked why they did not hear of return cases of diphtheria, a disease in which the bacillus often remained long after convalescence and throat symptoms recurred, and still less of returns in small-pox?

Dr. SWEETING and Dr. PRINGLE upheld the "old clothes" theory and the apathy of the poor, who were terrified by small-pox, in which, too, the effect of re-vaccinations should be considered.

Dr. DOWNES, Dr. PARSONS, Dr. BOND, Dr. BULSTRODE, Dr. G. BUCHANAN, and Dr. SIDNEY DAVIES continued the discussion, calling attention to the influence of school attendance.—Dr. Buchanan would limit the return cases to those occurring within eight days, and insisted on the greater persistence of the scarlatinal poison, though return cases of diphtheria were not unknown. They agreed as to the need for exhaustive investigation of the bacteriology of the skin, throat, and urine, with the view of determining the means and duration of infection.

HUNTERIAN SOCIETY.

Congenital Ataxia.—Exhibition of Cases.

AN ordinary (clinical) meeting of this society was held on Nov. 13th at the London Institution, the President, Mr. C. J. SYMONDS, being in the chair.

Dr. F. J. SMITH read for Mr. MCDONNELL the notes of a case of Congenital Ataxia in a boy six years of age.

Mr. TARGETT showed a boy aged five in whom he had excised one temporo-maxillary articulation for Ankylosis following Otorrhœa.

Dr. J. H. SEQUEIRA showed a case of Nystagmus with Facial Paralysis in a girl aged eleven, present since the age of two.

Dr. ETTLES showed—(1) a case of Horizontal Nystagmus cured by correction of the astigmatism present; (2) a case of Distension of the Left Frontal Sinus in a woman aged fifty-eight; and (3) a case of Hyperexophoria with Divergent Strabismus and without Diplopia.

Dr. F. J. SMITH showed a case of Paroxysmal Hæmoglobinuria with Local Syncope and Asphyxia.

Mr. OPENSHAW showed a girl aged seventeen with patches of Local Asphyxia on Toes and Heels.

Sir HUGH BEEVOR showed two cases of Cervical Herpes followed by severe pain, and a case of Fibroid Phthisis of the Right Lung in a boy four years old.

A case was shown for Dr. GLOVER LYON of Imperfect Development of the Pinna of the Right Ear.

Mr. COTMAN showed a man with peculiar Thickening of

Digitized by Google

the Left Ankle, arising from traumatism, but with no pain or other sign except the thickening of the tibia and fibula at the joint.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held in the Great Northern Central Hospital on Nov. 14th, Mr. CHARLES KING being in the chair.

Mr. G. MOWER WHITE showed three cases of Fracture of Bones having points of interest. The first was an ununited fracture of the humerus occurring in a woman forty-seven years of age, in whose history no evidence of syphilis was ascertained. On account of failure to obtain union in the first instance, the ends of the bone were fastened together by means of ivory pegs. After a considerable period of immobilisation union had not resulted, and the portions of ivory in the tissues had become absorbed. The next method of treatment adopted was securing the ends of the bone by short rods of nickel. As bony union still failed to occur, the ends of the fragments were exposed and portions of fresh rabbit's bone were placed within the periosteum. Union still failed to be brought about, and the speaker said that he seemed to have arrived at the end of the justifiable methods of treatment.—Mr. C. KING, Mr. CRESSWELL, and Dr. GALLOWAY discussed the case, and all concurred in the opinion that syphilis might possibly have something to do with this remarkable failure of union.

Mr. WHITE then showed two cases of Fractured Patella, the one treated by means of a back splint and approximation of the fragments by kneecaps and bandaging, and the other treated by means of wiring the fragments. The superiority of the latter method was readily appreciated, both in the character of the result obtained and in the great shortening of the period of convalescence.

Dr. E. C. BEALE brought forward the case of a young girl about twelve years of age who had suffered from repeated attacks of Gastro-enteritis. The stools showed numerous flecks of hæmorrhage, and at the same time the child had suffered from attacks of purpura. At present she was in a period of quiescence, so far as the gastro-enteritis was concerned, but the purpura was still to some extent visible; the skin showed numerous papules on the sites of the original purpuric spots. Dr. Beale felt inclined to ascribe all these symptoms to poisoning by faulty ingesta, and that the enteritis was in this case an inflammation of the mucous follicles, as evidenced by the numerous minute hæmorrhages present throughout the stools.

Dr. JAMES GALLOWAY showed a patient suffering from Chronic Phthisis who had for five years been the subject of a curious variety of Lichen Planus. The eruption, mainly on the extremities, was of the circinate variety, and in many respects resembled some of the later superficial syphilides. This patient had been treated for nearly ten months with guaiacol in the form of the carbonate and also as a solution of the pure product. The tuberculosis had passed into a quiescent condition, and the skin eruption was better than it had been during the last five years.

Cases of Embolism of the Arteria Centralis Retinæ associated with Albuminuric Retinitis, and a case of almost complete Optic Atrophy following a blow on the head were also demonstrated.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Adjourned Discussion on Gastric Ulcer.

A MEETING of this society was held on Nov. 15th, Dr. A. SYMONS ECCLES, President, being in the chair.

Mr. KEETLEY said that in cases of perforation not diagnosed early enough it was clear that confusion with colic or "stomach-ache" seldom arose, and that, though peritonitis was recognised, the mistake was made of not at once determining the cause and dealing with it.

Mr. MCADAM ECCLES laid stress on the value of drainage in cases of escape of the gastric contents, and for this purpose he makes a second opening lower down, which he keeps open for twenty-four to thirty-six hours.

Dr. CLIPPINGDALE discussed the etiology of gastric ulcer and assigned a leading place to local constriction in women by corsets and in men by belts.

Mr. SWINFORD EDWARDS raised the question of the value of gastric endoscopy for diagnosis previously to perforation, and narrated a case of a middle-aged man who had a copious discharge of bright-red blood from the rectum. No gastric symptom was present, but at the necropsy perforation of the right gastro-epiploic artery was the only lesion found.

Mr. R. W. LLOYD discussed the dietetic and medicinal treatment, and called attention to the varied localisation of pain in the cases where perforation afterwards occurred.

Dr. ALDERSON thought that local counter-irritation was a valuable adjunct to treatment.

Mr. BIDWELL referred to the operative treatment in non-perforating cases. He mentioned a case where operation had been performed for persistent symptoms, and others where the symptoms were due to adhesions either within or without the stomach in consequence of the cicatrisation of an ulcer. Considering the uncertainty of the diagnosis of perforation, he held that an operation ought to be performed unless the physician can assure himself that the case is not one of gastric ulcer.

Mr. SNAPE asked the opinion of surgeons present as to the advisability of operating in severe cases before perforation.

Mr. BRUCE CLARKE, in reply, said that in cases of hæmorrhage threatening the life of the patient he would follow the ordinary surgical indication and cut down on the bleeding points.

Dr. ABRAHAM called attention to a singular appearance in Dr. Alderson's case—i.e., that the stomach walls appeared microscopically to be infiltrated with cells somewhat resembling those of a pigmented sarcoma.

Dr. LAWRENCE urged the value of albuminate of iron.

Dr. PEARSON thought that some cases of gastric hæmorrhage in girls might be assigned to vicarious menstruation.

The PRESIDENT summed up briefly, and regretted that no speaker had been able to distinctly define the various indications for operation.

LIVERPOOL MEDICAL INSTITUTION.

Is Cancer Curable by Surgical Operation?—Successful case of Cholecystotomy.

AN ordinary meeting of this society was held on Nov. 14th, the President, Mr. CHAUNCY PUZEY, being in the chair.

Dr. DAVIES—in opening the discussion on Is Cancer curable by Surgical Operation?—said that evidence goes to prove that cancer is something far other than a mere local disease. In fifty-three cases of uterine cancer submitted to the operation of complete hysterectomy there was early recurrence in almost every instance. Numberless authorities advocate and describe partial or complete hysterectomy, but their writings do not contain the facts as to the actual benefit derived from the operation. In his opinion patients with recurrence of the disease suffer more acutely than those in whom it has never been touched. He thought that cancer was most probably a micro-parasitic disease in the blood. In his opinion alimentary cancer was as unsatisfactory as the uterine form, and more reliable details of results were much needed. He also thought that the subsequent and remote results of operation on breast cancer were very bad, notwithstanding that the operation was becoming more and more severe, with clean sweeping of the axilla and even removal of the arm. Statistics, immediate and remote, would be a great help. There was no evidence that cases of non-recurrence were also examples of early operation. Patients ordinarily live for two or three years whether treated by surgery or left alone. When cases live for ten or twenty years after operation the question to determine was whether the case was ever one of cancer at all. Dr. Davies, in concluding, advocated the serial and methodic investigation of a large number of cases, extending over many years, such investigation to be duly audited by a competent committee.

Mr. PAUL said that he had no intention of advocating either side of the debate, but hoped to state his views impartially. He thought there was no such diversity in *practice*, as had been suggested by Dr. Davies, amongst the leaders in surgery. Having given the facts upon which his views were based, he expressed the opinion that cancer was local in origin, but could only occur in tissues favourably

Digitized by Google

predisposed to its growth, and that it could be cured in the same sense that a tuberculous joint could be cured by excision. He then proceeded to give the results of surgical treatment in cancer of the alimentary tract. The best successes quoted were in cancer of the lip, gums, cheek, rectum, and anus, but he believed the colon and pylorus would yield equally good results in time. Finally, he considered that surgical success depended upon—(1) early recognition, (2) thorough extirpation, (3) inherent favourable tendencies in the tumour, and (4) judicious constitutional after-treatment.

Mr. BANKS dwelt more particularly on cancer of the breast. He said that he could well remember the time when cancer was held to be an absolutely constitutional disease, but later many veered round to the opposite opinion and alleged that it was purely a local malady. He believed in a cancerous diathesis, but thought that some local irritation was necessary to start the disease; if, however, the portion of the economy so affected could be clean scooped out, "like the bad bit out of an apple," there was no absolute reason why the disease should not be eradicated. If once it is admitted that cancer is a purely diathetical disease, the surgeon may give up all attempts at its removal, for, whatever is done, it will return locally or at a distance; on the other hand, if he believes too implicitly in a mere local focus which spreads and affects the system, he will often be led away into rash and futile operations which can never, in the nature of things, succeed and which do serious harm by prejudicing certain operations in the minds of the public, both medical and lay. Mr. Banks confessed that the only remedy at present, if one was employed at all, was the knife, and that admittedly a very poor one. When a student he was taught that if there was secondary infiltration of the glands this was a bar to all operative procedure, but about eighteen years ago he had begun to practise a much more free local removal of the breast, accompanied by a clearing out of the axilla. He believed that if this could be thoroughly done it was a perfectly justifiable operation. He thought that if they could only get people to come early enough with their breast tumours and have them removed they might save one out of four from further invasion. While, therefore, he deprecated reckless and useless operation, he would regard anyone who should refuse absolutely to remove breast cancers on any consideration as a person perfectly devoid of reason and common sense.

Mr. W. S. CRAWFORD advocated the treatment of certain cases of mammary cancer by surgical means. He gave particulars of four cases, microscopical sections of which had been shown. In one the patient died five years after he operated and without any return of the cancer; the second case was now living, three and a half years after operation, with no apparent return; the third case died three and a half years after operation from other causes; and in the fourth a different form of cancer attacked the second breast three years after the first one was removed.

Dr. IMLACH said that, according to some modern "localists," out of 500 operations for cancer 100 remained free from recurrence, while, according to Sir James Paget, perhaps only one individual would remain free. He was surprised at the meagre information which was supplied by the supporters of hysterectomy for cancer. Surgeons generally complained that patients with cancer are not sent to them sufficiently early, but he believed, with Dr. Davies, that cases of non-recurrence were very seldom examples of early operation. If any hospital committee, disappointed with the results of cancer surgery, desired an inquiry into results they should carry it out for themselves, with the aid of medical assessors.

Dr. ALEXANDER admitted that the results of operation for cancer were not satisfactory, but there could be no doubt that surgery was sometimes a "cure" for the disease, and he cited some cases from his practice to prove this point. Apart from "cures," surgery gave distinct relief, especially in cancer of the tongue and rectum, where recurrences took place outside the alimentary tract and killed the patient by exhaustion without the terrible agonies experienced by those who died unrelieved by operation.

Mr. BRIGGS, Mr. J. D. CRAWFORD, Mr. ROBERT JONES, Dr. WALLACE, Dr. CARTER, Dr. RAWDON, and Mr. RUSHTON PARKER also took part in the debate.

Mr. CLEGG showed a female patient aged twenty-six years from whom he had successfully removed several Stones from the Gall-bladder.—Dr. RAWDON and Dr. O'HAGAN made remarks on this case.

MANCHESTER MEDICAL SOCIETY.

Cervical Pachymeningitis.—Pulsating Orbital Swelling.—Abscess of Spleen.—Ipecacuanha Alkaloids.

A MEETING of this society was held on Nov. 6th, the President, Mr. F. A. SOUTHAM, being in the chair.

Dr. LEECH showed a case of Cervical Pachymeningitis. The patient came under his care nineteen years ago, being then fifteen. He was suffering from loss of power over both arms and the left leg. Prior to the paralysis he had suffered from an abscess at the back of the neck, and from a sinus it left a piece of bone of considerable size had been discharged. Soon after admission into the Infirmary power was entirely lost in the arms and legs, the muscles were rigid, the deep reflexes much exaggerated, and tremors were easily produced. The muscles of the upper extremity were wasted, and there was characteristic deformity of the hands. He had incontinence of urine, and some anæsthesia. The boy remained completely paralysed for many months, yet he eventually recovered. He could not stand for two years, and three years elapsed before he could walk. For sixteen years he has remained well and able to work. The right hand is a little deformed, and the reflexes are unduly marked—otherwise he is in good health.

Mr. JONES showed a case in which both Common Carotid Arteries had been tied for a Pulsating Swelling in the Right Orbit. The patient, a woman aged twenty-four, was confined in January, 1891, after a tedious labour of thirty-six hours. Immediately after the birth of the child the patient noticed a peculiar noise in the head, which she compared to a loud knock at the door. This sensation was most noticeable on the right side of the head, and it was not attended with any pain. Fourteen days later both eyes became swollen, but the condition did not persist in the left eye. A little later the right eye began to protrude, and after two months the protrusion was most noticeable. She was under treatment for a few weeks, which consisted of rest in bed and intermittent pressure on the right carotid artery, no benefit being derived. She was admitted into the infirmary in December, 1891. The symptoms usually associated with orbital aneurysm were present in a more or less marked degree. Ligature of the right common carotid artery was practised in August, 1892, after a further trial of digital compression of the artery had been resorted to. The patient made a good recovery, and there was a marked improvement in her condition for a time until a violent attack of coughing, which was attended with much straining. Pulsation and the other symptoms returned in the orbital swelling. Her condition remained stationary for many months, when she received an accidental blow from a child's elbow, and an aggravation of the symptoms followed. She was readmitted last January, and as it was found that the pulsation in the swelling could be controlled by pressure on the left common carotid artery this vessel was secured. The benefit accruing from this operation was of a very temporary character. Her condition now is very much what it was when she first came under observation, and the question was discussed whether injection of coagulants into the dilated pulsating veins would not be a justifiable proceeding. If the patient gives her consent she will be again admitted for further treatment.

Mr. JOSEPH COLLIER mentioned a case of Abscess of the Spleen in a woman aged forty-five years, married, with no history of injury, who had never lived abroad, and who was admitted into Crumpsall Hospital with signs of left pleurisy. Later there existed a high temperature, much pain in the left side, and afterwards bulging in the left hypochondrium, which increased, was fluctuant, and slightly pulsating. Abscess of spleen was diagnosed, with hæmorrhage from the splenic substance into its cavity. The patient was in a very low condition; the abscess was opened, and over a pint of blood-stained pus, blood-clot, and broken-down spleen substance was removed; the hæmorrhage from the remaining portion of the spleen was easily controlled by pressure with a sponge towards the hilum; the remainder of the spleen was scraped out with a lithotomy scoop. The cavity was packed with iodoform gauze. There was no further bleeding, but the patient died from collapse in twenty-five hours. At the necropsy no peritonitis was found, but the peritoneum was pushed down by the abscess; there had been no hæmorrhage into the large abscess cavity. Left basal pleurisy was

Digitized by Google

present, with some clear fluid in the cavity. No other abscesses were found, nor was there any endocarditis, any evidence of pyæmia, tuberculosis, or syphilis, or any pyelophlebitis. The abscess was apparently idiopathic.

Dr. R. B. WILD read a paper on the Pharmacology of the Ipecacuanha Alkaloids (a full account of which is given on pp. 1274-77 of our present issue), in which were detailed the results of a number of experiments upon emetine and cephæline, the two alkaloids recently described by Paul and Cownley.

EDINBURGH OBSTETRICAL SOCIETY.

President's Address.—Atresia Vaginæ.—Teratogenesis: an Inquiry into the Causes of Monstrosities.—Election of Office-bearers.

A MEETING of this society was held on Nov. 13th, Dr. A. H. FREELAND BARBOUR, President, being in the chair.

The PRESIDENT in his Valedictory Address reviewed the work of the past session and referred to the loss sustained by the decease of some of the members. Regarding the work of Dr. Thomas Keith, few to-day could realise what it meant to persevere with the operation of ovariotomy when success was doubtful and in face of hostile prejudice until it was established as an operation above criticism. He was a pioneer who dared to go where no one had gone before. He had indomitable spirit, and combined with it a womanly consideration for the well-being of his patients. Dr. Leishman, Dr. Goodall, Dr. T. A. G. Balfour, Dr. D. Wilson, and M. Pasteur were also referred to.

Dr. R. C. BUIST (Dundee) read notes and showed a specimen of a case of Atresia Vaginæ. The patient died at forty-three, and had been operated on in her teens for retained menses, and again later; but she had not been able to work after thirty. She had menstruated regularly, and had suffered from a severe flooding in January of this year. Post mortem the uterus was found to be of normal consistence, seven and a half centimetres long; the cervix was small and opened into a small vagina three and a half centimetres long and of the same width, and funnel-shaped. On passing a probe down the vagina it appeared at the bottom of a deep pit in the urethra; and it was from this that the patient menstruated. The labia were normal, and on separating them a mass of cicatricial tissue could be felt. The tubes and ovaries were normal; below the left ovary a small fish-bone was found embedded.

Dr. J. W. BALLANTYNE commenced a series of papers on Teratogenesis: an Inquiry into the Causes of Monstrosities. Part I.: The Theories of the Past—(1) Supernatural Causes: (2) Physical Causes; and (3) Mental Influence. The subject had been engaging his attention during the last eight years, and he had examined 160 cases of monstrosities. Some of the views held by the ancients regarding their cause had long since been abandoned, and are now to be met with only amongst savage races; others are still accepted by the popular mind; and some have received a degree of justification by clinical and pathological investigations. Modern experimental research in the artificial production of monstrosities has done more than any other method to give a rational explanation for their causes. 1. Supernatural Causes.—Some ancient peoples ascribed monstrous births to the gods they worshipped; other races, who had divided their pantheon into good and evil deities, put the blame sometimes upon the former and sometimes upon the latter; whilst others connected their births with the positions and combinations of the stars and heavenly bodies. In succeeding ages the different deities, Satan, and evil spirits as well as the stars were alleged as the cause of monstrous births. According to some the gods were amusing themselves, or exhibiting their creative powers, or were angry with men, or chastising individuals or countries. The belief soon followed that these births were portents of good or evil fortune. The Chaldean astrologers soon advanced the opinion that such a babe of doubtful sex meant an approaching calamity to the land, whilst one with an imperforate anus proclaimed a famine. Similar beliefs held sway in Europe in the Middle Ages combined with the Satanic origin of such progeny. The mother of such a child strove to show the cause was in the stars, or a death at the stake awaited her and her "Devil's brat." In the earliest ages, on the hypothesis that these infants might be gods themselves or their progeny, it is easy to account for the teratological appearance of nearly all the heathen gods and goddesses. Many are unlike the cases of monstrosity seen now, but probably the artificer was never an eye-witness of the appearance and only received distorted details from those unacquainted with anatomical figures. Yet malformations well known at the present day can be recognised in the two-headed, many-breasted gods of the East—in Ptah of the Egyptians, in the Cyclops of the Greeks, and in the fauns and satyrs of the Romans. According to some Jupiter was amusing himself, and Pliny stated that nature creates monsters to astonish us and amuse herself. This idea is still implied in "freaks of nature" or "sport" in botany. Further on, the birth of a deformed fœtus was a divine warning, and with this was associated the necessity for propitiating the deity, and so the infant was sacrificed. In Europe almost all were immediately killed in the Early and Middle Ages, and the mother was fortunate if she escaped. Lucan relates that Arnus, chief of the Etruscan diviners, ordered the slaughter and burning of all monstrous infants at the time of the overthrow of the Roman Republic. The idea that monstrous births predicted disaster held its ground in Europe till the close of the seventeenth century. At other times they were regarded as a punishment of sins committed. In early French history Robert II. married his cousin and was excommunicated by the Pope. His wife gave birth to a malformed fœtus, evidently with webbed digits. She was divorced and the king took another wife. Another idea was that teratogenic power was specially the possession of an evil spirit. Du Chaillu, in his work on the Vikings, states that every child "which is born so deformed that the mother cannot give strength to it, shall be carried to a beach and buried where neither man nor cattle go—that is, the beach of the Evil One." In the early Christian era such fœtuses were looked upon as the progeny of Satan, and to destroy them was to destroy his family. In the sorcery and witchcraft trials in the Middle Ages "coitus cum diabolo" was always inquired into, and in many cases torture wrung most revolting confessions from the accused. Something of this view was in existence at the time of Luther; and as recently as 1893 a notice appeared in a newspaper concerning the birth of a hirsute and otherwise deformed infant supposed to be the result of incautious remarks about the Evil One made by the mother in her pregnancy. An astrologer of the second century not only stated the astral conditions under which terata were born, but also mentioned the nature of the malformation expected. A Danish astronomer, who was also a medical man, ascribed them to comets, and regarded them as tumours scattered throughout the firmament and precipitated on earth in this form. About the year 1200 a cow gave birth to a calf said to be half human, and the shepherd was accused of an unnatural crime and was condemned to be buried alive. Albert the Great saved him by stating that it was due to a certain constellation. Such beliefs were dispelled by the advancement of scientific knowledge, but traces of these early superstitions are to be found not only amongst savage races, but also in our own land and in the popular mind.

The following office-bearers were elected for the ensuing session:—President, Dr. A. Ballantyne (Dalkeith); Vice-Presidents, Dr. Halliday Croom and Professor A. R. Simpson; Treasurer, Dr. Craig; Secretaries, Dr. J. W. Ballantyne and Dr. F. W. N. Haultain; Librarian, Dr. Milne Murray; Editor of Transactions, Dr. J. W. Ballantyne; Members of Council, Dr. Lucas, Dr. Menzies, Dr. Stewart Stirling, Dr. Keppie Paterson, Dr. A. H. F. Barbour, Dr. James Ritchie, Dr. Andrew Balfour, and Dr. J. Jamieson.

GLASGOW SOUTHERN MEDICAL SOCIETY.

Treatment of Phthisis Pulmonalis.

AT the third meeting of this society, Dr. ALEXANDER RANKIN in the chair, a paper on the Treatment of Phthisis Pulmonalis was read by Dr. EBENEZER DUNCAN, detailing the treatment he had employed in 38 cases of phthisis pulmonalis under his care in the Victoria Infirmary, Glasgow, during the past year. Excluding 2 patients moribund on admission, of the remaining 36, 4 recovered, 9 were greatly improved, 16 improved, 6 remained *in statu quo*, and 1 became worse. The most important therapeutical factors were pure air (air washed and filtered before entering the wards) and an equable temperature. Medicinally, counter-irritation and antipyretics (if necessary) were employed in

Digitized by Google

the acute stage; later, inhalation frequently of a mixture of creasote, eucalyptol, and pinol in equal proportions. Internally, carbonate of guaiacol and beechwood creasote were exhibited. Beginning with small doses, 60 to 90 gr. of guaiacol were administered four times daily without detriment, and of creasote 25 minims in olive oil. Creasote had also been given as a suppository. Pure guaiacol had no advantage over the carbonate; applied to the skin (20 minims in flannel covered with oiled silk) it brought down the temperature—in one case to 96° F., with symptoms of collapse. Phenol was found in the urine when the maximum dose was reached, without impairing the renal functions. In one case in which there was acute nephritis the blood and albumin disappeared while the patient was taking large doses of the carbonate of guaiacol. There was no gastric disturbance with either drug. When a large cavity existed, intra-laryngeal injections of menthol (15 per cent.) and guaiacol (4 per cent.) in olive oil—the patient lying on the affected side—had been employed with benefit. Cod-liver oil and a generous diet completed the measures.

In replying after the discussion which followed Dr. DUNCAN advocated the erection of a hospital in Glasgow by the municipal authorities for the treatment of tuberculous diseases.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Colotomy.

A MEETING of this section was held on Nov. 8th, Sir W. THORNLEY STOKER, President, being in the chair.

Mr. WHEELER read a communication upon Colotomy, recommending it prior to excision of the rectum for cancerous disease in cases where there were much rectal irritation, diarrhœa, pain, and consequent nervous exhaustion. He considered anterior colotomy preferable and safer, although the lumbar operation had its own place in surgery. As the peritoneum not infrequently surrounds the entire bowel, one of the advantages claimed for the lumbar operation cannot always be upheld. He recommended the parietal peritoneum to be sutured to the wound and a needle armed with a suture passed through the mesentery and then carried through the parietal peritoneum on each side—the gut having previously been drawn through the wound; he sutured back the mesentery at the distal side of the gut to the parietal peritoneum sufficiently to prevent procidentia, which plan was much preferable to drawing the intestine in quantity outside the abdomen and ultimately cutting it off, a procedure sometimes inadmissible; when there was a short mesentery, in addition to the above he passed a sterilised bougie through the mesentery below the suture and allowed it to rest across the wound external to the abdomen; this helped in the formation of a more perfect spur so essential for the after-comfort of the patient. He deprecated the practice of dividing the gut, suturing the lower end, and then dropping it into the abdomen, enumerating the disadvantages and dangers. He described a transverse colotomy for obstruction at the splenic flexure of the colon which was ascertained by an exploratory incision and believed at the time to be malignant, but the patient is at present alive and well, nearly three years after the operation. He also described a left inguinal colotomy for cancerous prostatic disease causing obstruction; the patient died thirteen months after the operation.

Mr. HENRY GRAY CROLY read a paper on Left Lumbar Colotomy, and stated that he had, during the past twelve years, performed that operation eighteen times. With one exception, the operations were performed for cancer of the rectum, and the cases were unsuited for excision; no death occurred from the operation. Two of the patients (notwithstanding careful antiseptic precautions) were attacked with erysipelatous inflammation and septic or erysipelatous pneumonia, but recovered. In each case great relief was afforded to the sufferers. The patients lived from a few months to over two years; one man worked for nearly two years after the operation as a labourer. All the patients became fat and expressed themselves as grateful for the relief afforded to their sufferings. Mr. Croly said he did not intend to compare the lumbar operation with the now more fashionable inguinal operation, but thought it his duty to place on record brief notes of the cases. He adopts the oblique incision of Bryant, and in his hospital practice marks out the crest of the ilium, last rib and erector spinæ muscles; he has invariably found the colon half an inch behind the centre of the crest. He opens the intestine at once and makes an opening not longer than half an inch, thus preventing the prolapsus which occurred in some of his early cases. On one occasion the gut was collapsed and the kidney presented, but the intestine was soon found; in two cases the distance between the crest of the ilium and the last rib was very short, and consequently the wound was deep. He claimed for lumbar colotomy its extra-peritoneal advantage, and he considered the position of the artificial anus in the loin less unpleasant to the patient than the inguinal.—The PRESIDENT expressed surprise that lumbar colotomy should be advocated at the present time.—Sir WILLIAM STOKES said that the more experience he had of lumbar colotomy the more highly did he think of it, although he did not think ill of the anterior operation. One advantage of the lumbar over the inguinal operation was that, as the patient had to lie on his back for a considerable period after the operation, there was a better chance of fæcal drainage. The anterior operation had, however, the advantage of the greater facility and comfort by which the toilet of the patient could be performed.—Mr. KENDAL FRANKS said that the extended use of excision of the rectum, especially by the trans-sacral method, was gradually turning colotomy out of the field, so that colotomy, he believed, would soon become a very exceptional procedure.

Reviews and Notices of Books.

Lectures on Diseases of the Spinal Cord. By Dr. PIERRE MARIE. Translated by MONTAGU LUBBOCK, M.D., F.R.C.P. Lond. London: The New Sydenham Society. 1895.

THE French school of neurology, which was practically founded by the late M. Charcot, has achieved much, not only through the additions to science that have proceeded from it, but also from the impetus it has given to systematic study of diseases of the nervous system all over the world. This widening of interest in a subject abounding in matter for observation has been in large measure due to the methods and style of presentation of it by Charcot and his pupils, among the most eminent of whom is the author of the work before us. The clinic of La Salpêtrière furnished M. Charcot abundant material for study, and the volumes of his lectures will always remain as among the most exact as well as the most lucid expositions of the various phases of nerve disorders. Dr. Pierre Marie has in these lectures, which the New Sydenham Society has done well to place in its series, followed the lines laid down by his master, and has produced a work which is worthy to rank with those of Charcot. The volume consists of thirty-eight lectures, which cover the ground of diseases of the spinal cord, each topic being treated with a fulness and precision that leave little to be desired. Opening with a lecture devoted to the consideration of the anatomy of the pyramidal tract, the author next proceeds to describe in turn the subjects of secondary degeneration of the pyramidal tract, of descending degeneration consecutive to transverse lesions of the cord, ascending degeneration consecutive to lesions of the nerve-roots, and to transverse lesions of the cord. Two lectures are devoted to the interesting subject of degeneration of the nerves and spinal cord after amputation of a limb, and, after a discussion of the various conflicting views as to the cause of such secondary changes, the author himself suggests that they are of the nature of an ascending neuritis through the absorption of "some morbific agent" at the extremity of the divided nerve. This explanation, he admits, is as hypothetical as any of the others, but thinks that it receives some support in the analogy of sympathetic ophthalmia. The clinical description of the diseases

Digitized by Google

of the cord begins with spastic paraplegia, and full recognition is made of the writings of the late Dr. Little, which preceded by many years the observations of neurologists. Its congenital character, and its frequent occurrence in children of premature birth, point to the dependence upon some defect in development, and this has been reasonably supposed to be an arrest of growth of the pyramidal tract, often due to injuries inflicted at birth or fœtal inflammation of the meninges or the brain. The author distinguishes between the "true spastic paraplegia" and the "tabetic spasmodic conditions," the former being those due to mere arrested growth, the latter those due to injury and inflammation and associated with mental defects—epilepsy or other sign of cerebral lesion. In spite of the apparent hopelessness of remedying a condition dependent on the non-development of the pyramidal tract, Dr. Marie says that much may be done to excite normal function in those fibres that have formed, and he points to the results achieved by Bourneville at the Bicêtre by gymnastics, massage, &c., carried on with perseverance, as showing that "much improvement may be obtained in cases of spasmodic cerebral pseudo-paralysis, even when complicated by more or less pronounced idiocy." The lectures upon "Insular Sclerosis" recall the memorable picture of this disease given by Charcot in the first volume of his "Leçons." It is treated here in a systematic manner, and the opinion is expressed that this affection really arises from the action of infective agencies. The distribution of the sclerosed patches suggests a vascular origin, and this may be of the nature of embolism, caused by the influence of several infectious diseases. The *pièce de résistance* of the book is undoubtedly to be found in the chapters dealing with the subject of Tabes Dorsalis, which is treated with remarkable detail, and illustrated by a wealth of clinical and pathological facts. The symptomatology of this common yet remarkable affection are described in regular sequence under the heads of Motor, Sensory, Reflex, Trophic, and Visceral. The trophic disorders comprise a very full account of tabetic arthropathy, and an especial description of the "tabetic foot," besides many another lesion of nutrition that keen observation has caused to be added to the list. Lastly, it is instructive to note that Dr. Marie agrees with those who assign to syphilis the chief agency in the causation of tabes—not, be it noted, as affecting the interstitial substance, but as a direct intoxication of nerve cells, for he says, "It is only in this way that we can explain the fact that cells, as distant from each other as are those of the spinal and peripheral ganglia, are simultaneously affected by the same morbid process and in the same special elective manner." The subjects of Friedreich's disease, combined lateral and posterior sclerosis (ataxic paraplegia), spinal paralysis (infantile and adult), infantile paralysis, and amyotrophic lateral sclerosis are also dealt with. The translation of the work has been admirably rendered by Dr. Montagu Lubbock, and an index is added which forms in itself an excellent digest of the contents of the book. It is to be regretted that many of the figures in the text—and their whole number is commendably large—should have apparently suffered so much in reproduction.

Dictionary of National Biography. Edited by SIDNEY LEE. Vol. XLIV.: Paston—Percy. London: Smith, Elder, and Co. 1895.

SIR ROBERT PEEL, the statesman, is probably the most notable figure in this well-stored volume. An estimate of his eminent public services rendered during a political career of nearly forty years would be out of place in the columns of a medical journal; it may be sufficient to observe that he was born in Lancashire in 1788, entered the House of Commons in 1809, was Chief Secretary for Ireland from July, 1812, to August, 1818, and Prime Minister from August, 1834, to June, 1846. He died in London in July, 1850, from injuries received by falling from his horse a few days previously. His father, Sir Robert Peel, the first baronet, was a partner in a calico-printing firm in Blackburn. He represented Tamworth in the House of Commons, and in 1802 carried the Act which was the forerunner of all factory legislation—"an Act for the preservation of the health and morals of apprentices and others employed in cotton and other mills, and cotton and other factories."

No fewer than twenty-three medical men are included among the subjects of biography, several of them being honoured with titular distinctions and positions of dignity in their profession. Thomas Pellett was born in Sussex about 1671, graduated as M.D. at Cambridge in 1705, and resided in Henrietta-street, Covent-garden. He was elected a Fellow of the College of Physicians of London in 1716, was Censor in 1717, 1720, and 1727, and President from 1735 to 1739. The Harveian Oration delivered by him in 1719 is remarkable as the only published one which is partly in verse. He died in 1744. Sir Lucas Pepys was born in London in 1742, studied medicine at Edinburgh, obtained from Oxford University a pre-graduation licence to practise, and became physician to the Middlesex Hospital in 1769. He graduated as M.D. at Oxford in 1774, was elected a Fellow of the College of Physicians of London in 1775, was Censor in 1777 and three subsequent years, Treasurer from 1788 to 1798, and President from 1804 to 1810. In 1777 he was appointed Physician Extraordinary to King George III. and attended him during his mental disorders of 1788–89 and 1804, spending two days a week at Kew with the King, from four in the afternoon till eleven the next morning. He had a large practice and was an active supporter of the National Vaccine Institution, but his only published work was the Latin preface to the London Pharmacopœia of 1809. He was created a baronet in 1784 and died in 1830. Sir Christopher Pegge was born in London in 1765, graduated as M.D. at Oxford in 1792, was knighted in 1799, and in 1801 was appointed Regius Professor of Physic in Oxford. He was elected a Fellow of the College of Physicians of London in 1796, delivered the Harveian Oration in 1805, and became a Censor in 1817. He died in 1822. Sir Isaac Pennington was born in Lancashire in 1745, graduated as M.D. at Cambridge in 1777, and in 1793 was appointed Regius Professor of Physic there. He was elected a Fellow of the College of Physicians of London in 1779 and delivered the Harveian Oration in 1783. He was knighted in 1796 and died in 1817, leaving munificent bequests to St. John's College, Cambridge. Robert Perceval was born in Dublin in 1756, studied medicine in Edinburgh, and graduated there as M.D. in 1780. In 1785 he was appointed the first Professor of Chemistry in Dublin University and retained the office till 1805. In 1785 he took an active part in founding the Royal Irish Academy and was for a long time its secretary. In 1793 he received the degree of M.D. from Dublin University. In 1799 a committee of the Irish House of Lords was appointed to inquire into the application of the funds left by Sir Patrick Dun, and Perceval in the course of his evidence declared that he did not think that the King and Queen's College of Physicians, of which body he was a Fellow, had faithfully discharged its trust in this matter. On the report of this committee the "School of Physic Act" was passed in 1800, and Sir Patrick Dun's Hospital, built from the surplus funds of Dun's bequest, was opened in 1808. Perceval was elected President of the King and Queen's College of Physicians in 1799, but vacated his Presidency and Fellowship under a subsequent regulation, promoted by himself, according to which no University or King's professor could remain a Fellow of the College. He afterwards became an active member of the "Prison Discipline Society" and was called "the Irish

Digitized by Google

Howard "; he published several unimportant works, but was a successful physician. He died in 1839. Granville Sharp Pattison, born in Glasgow in 1791, received the diploma of the Faculty of Physicians and Surgeons of that city in 1813, and in 1820 was appointed to the chair of Anatomy, Physiology, and Surgery in the University of Maryland in Baltimore. He returned to England in 1827 and for a short time was Professor of Anatomy at the University of London (now University College). This post he relinquished in 1831 and in the same year became Professor of Anatomy in the Jeafferson Medical College, Philadelphia, where he received the degree of M.D. He was appointed Professor of Anatomy in the University of New York in 1840, and continued to hold office till his death in 1851. He edited various American medical periodicals, and published "Experimental Observations on the Operation of Lithotomy." The most conspicuous scientific worker among the medical men noticed in this volume was Thomas Bevill Peacock, who was born at York in 1812, his parents being members of the Society of Friends. In 1833 he came to London, studied medicine at University College and St. George's Hospital, spent some time abroad, and graduated at Edinburgh University as M.D. in 1842. In 1849 he became assistant physician to St. Thomas's Hospital, in 1850 he was elected a Fellow of the Royal College of Physicians of London, and in 1865 he delivered the Croonian Lectures there on Some of the Causes and Effects of Valvular Disease of the Heart. A dispensary originated by him in the City of London ultimately developed into the present Victoria Park Hospital for Diseases of the Chest, to which he was physician from its commencement. He was also one of the founders of the Pathological Society of London in 1846, and filled the offices of Secretary in 1850, Vice-President in 1852–56, and President in 1865 and 1866. Besides his Croonian Lectures above mentioned, he published treatises on the Influenza or Epidemic Catarrh of 1847–8, on Malformations of the Human Heart, and on the Prognosis in Cases of Valvular Disease of the Heart. He contributed numerous papers to the transactions of various medical societies, and was awarded a gold medal by the Royal College of Surgeons of England in recognition of his valuable additions to their museum. In May, 1882, while walking in St. Thomas's Hospital, he became suddenly unconscious, and died on the following day. George Pearson, born in Rotherham in 1751, studied medicine in Edinburgh and graduated there as M.D. in 1773. In 1784 he was admitted a Licentiate of the Royal College of Physicians of London, and in 1787 became physician to St. George's Hospital, where he lectured on chemistry, materia medica, and the practice of physic. He was among the first to recognise the value of Jenner's discovery of vaccination, and in 1799 a vaccine pock institution, with which Jenner had no connexion, was established by his efforts at 5, Golden-square, but when Jenner was rewarded by Parliament for his services Pearson was ignored, and subsequently took every opportunity of denouncing Jenner. He was physician to the Duke of York's household and a scientific chemist of much ability; the designation "uric acid" is said to be due to him. He died in 1828. John Pechey, admitted a Licentiate of the Royal College of Physicians of London in 1684, was admonished by the College in 1688 for distributing handbills and displaying a signboard; being recalcitrant, he was fined £4, and on a subsequent occasion £8. He published several works, the best known being an English translation of Sydenham's writings, which reached its eleventh edition in 1740. He is supposed to have died in 1716. Surgeon-General Saville Marriott Pelly was born in 1819 and passed the most active years of his life in India. The biographical notice of him is somewhat meagre, but readers of THE LANCET will find a full account of his career in that journal for April 20th, 1895. Christopher Robert Pemberton was born in Cambridgeshire in 1765 and graduated as M.D. at Cambridge in 1794. He was elected a Fellow of the Royal College of Physicians of London in 1796, was Gulstonian Lecturer in 1797, was Censor in 1796, 1804, and 1811, and delivered the Harveian Oration in 1806. He was physician to St. George's Hospital from 1800 to 1808, and physician extraordinary to the King. He was the author of a work entitled "A Practical Treatise on Various Diseases of the Abdominal Viscera," containing some important contributions to medical knowledge, and he died in 1822. Henry Pemberton, born in London in 1694, graduated as M.D. at Leyden in 1719, was appointed Gresham Professor of Physic in 1728, and from 1739 to 1746 was employed in the preparation of an edition of the London Pharmacopœia. He was, moreover, so accomplished a mathematician that he was engaged by Sir Isaac Newton to superintend the third edition of the "Principia," published in 1726. He was an industrious writer on a variety of subjects and died in 1771. Thomas Percival, born in Warrington in 1740, studied medicine in Edinburgh and Leyden, and graduated at the latter university in 1765. In 1767 he settled in Manchester and devoted much of his energies to the advocacy of sanitary improvements and factory legislation. The Manchester Literary and Philosophical Society was founded at his house in 1781, and he filled the office of President almost continuously from 1782 till his death in 1804.

Dorothy Wyndlow Pattison, daughter of a Yorkshire rector, and sister of Mark Pattison of Oxford University, was born in 1832. In 1864 she became, in opposition to her father's wish, a member of the Sisterhood of the Good Samaritan at Coatham, in Yorkshire, and adopted the name of Sister Dora. In 1865 she was sent to a small cottage hospital established at Walsall by the sisterhood, where she soon became familiar with the treatment of wounds and fractures, and acquired some knowledge of anatomy through regularly attending the post-mortem examinations. In 1877 she was placed in charge of the Municipal Epidemic Hospital at Walsall, occupied chiefly by cases of small-pox, but cancer had already shown itself and carried her off in the end of 1878. Patrick, the famous patron saint of Ireland, was born in Scotland in the year 373, his father being a magistrate in Dumbarton, which was at that time a fortress held by a Roman garrison. In 389 the youth was captured in a raid and carried off to Ireland, where he was sold as a slave, but after six years he escaped to France and spent several years there, probably with St. Martin of Tours. Having been consecrated a bishop, he commenced his mission to the heathen Irish probably in 405. The date of his death may be reckoned as 463, and, according to St. Bernard, he was buried at Armagh. Another evangelist of the heathen in our own generation was John Coleridge Patteson, first missionary bishop in Melanesia, who laboured among the South Sea islanders from 1865 until 1871 when he was killed by natives of the island of Nukapu in revenge for an outrage committed there by some Englishmen a few months before.

LIBRARY TABLE.

Outlines of Practical Physiology: being a Manual for the Physiological Laboratory, including Chemical and Experimental Physiology, with reference to Practical Medicine. By WILLIAM STIRLING, M.D., Sc.D., Edin, Brackenbury Professor of Physiology and Histology in Owens College and Professor in Victoria University, Manchester; Examiner in Physiology in the Universities of Edinburgh and London. Third Edition, revised and enlarged, with 289 Illustrations. London: Griffin and Co. 1895. 6s.—This is the third edition of an excellent manual which is admirably adapted for work in the physiological laboratory. While its essential features remain unchanged the subject matter has been rearranged in the present edition, and a considerable number of additions have been made, including a short appendix on

Digitized by Google

recording apparatus. The work is profusely illustrated, a large number of the illustrations being new and several of the woodcuts being from original drawings. The design is well conceived and the method and arrangement are good, and no pains seem to have been spared by its author to make it a sound and instructive handbook and guide for the student of science and medical practitioner.

A Woman's Words to Women on the Care of their Health in England and in India. By MARY SCHARLIEB, M.D., B.S. Lond. London: Swan Sonnenschein and Co., Limited. 1895.—This is a very good little book dealing wisely and well with a number of details which are necessary to be known in regard to the hygiene and health of women and children in this country and abroad. It is clearly and practically written, and will prove especially useful to those who are proceeding to India and the colonies. A large amount of preventable ill-health and discomfort is produced by the want of some knowledge of physiology and the laws of health and the exercise of a little timely care and foresight, and this want the book in question is calculated to supply.

Tours in the West Indies.—This is a handy little pocket guide giving the itinerary of the tours arranged for the winter service of the Royal Mail Steam Packet Company. In addition to the itineraries there are some useful notes on the chief points of interest attaching to the various islands, and there is a good map showing the routes taken by the company's steamers. Those who contemplate wintering in this part of the New World will find the guide, which is well illustrated, of service.

On Appendicitis and Perforation of Gastric and Duodenal Ulcer. Being the Ingleby Lectures for 1895. By GILBERT BARLING, F.R.C.S. Eng. Birmingham: Cornish Bros. 1895.—The subjects treated of in this little book have been so much to the fore of late that a clear exposition of diagnosis and treatment, with the appended catena of cases operated upon, both successfully and the reverse, is of great value. The impression left upon the reader is, undoubtedly, that operative interference is imperative the moment that there is reason to suspect the formation of pus. The necessity for freedom of drainage is also insisted on. Though, as the author says in his preface, there is nothing very new in his remarks, yet the clear way in which his facts are set forth make these lectures a valuable addition to the literature of the subject.

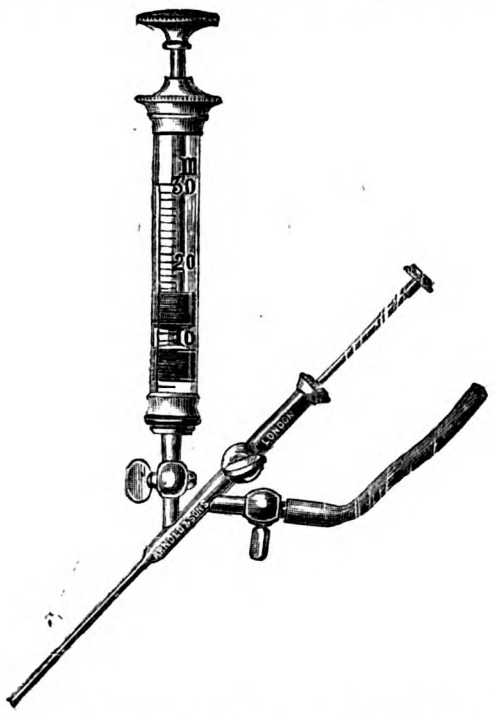
Vorlesungen über die Zelle und die einfachen Gewebe des Thierischen Körpers. Von Dr. R. S. BERGH, Docent der Histologie und Embryologie an der Universität Kopenhagen. Wiesbaden: C. W. Kreidel. 1894. (Lectures on the Cell and Simple Tissues of the Animal Body. By Dr. R. S. BERGH, Teacher of Histology and Embryology at the University of Copenhagen. Wiesbaden: C. W. Kreidel. 1894). London: Williams and Norgate. Pp. 262. Price 7*s.*—These lectures constitute an introduction to the study of histology which is fully abreast of the discoveries of modern research. They are clearly written and abundantly illustrated with figures, most of which are reproduced from the works of leading authorities on the subject. Commencing with a description of unicellular organisms, the morphology of the cell is given in detail. It is stated *en passant* that the disappearance of the nucleus from the cell—as in the red blood corpuscle—is to be regarded as a mark of degeneration, and hence the brief existence of such corpuscles. The finely fibrillar structure of cell substance is well illustrated, and the remarkable constitution of the nucleus, one of the most striking additions to knowledge made by microscopical investigation, is dwelt upon. The essential functions of the cell are summed up as consisting in movement, irritability, and metabolism, the two first-named properties being possessed by the cell substance, and the last named by the nucleus as well as the protoplasm. Then comes a description of the direct and indirect processes of cell division, the mechanism of fertilisation, and lastly the formation of deposits in and around cells. The rest of the work is concerned with an account of the animal tissues, epithelial (including glandular), muscular, nervous, and connective.

Physiology. By A. MACALISTER, M.D., F.R.S., &c. London: Society for Promoting Christian Knowledge.—This unpretending little book is one of a series of manuals of elementary science published by the Society for Promoting Christian Knowledge and the collocation of the publishers, and the subject is, we think, a happy one. It commences with a short and clearly put account of metabolism, diet, and cookery, leading to digestion and assimilation, and the author then passes by an easy transition to the circulation of the blood, which in its turn leads to respiration. Then follows an account of the tissues and the excretory glands as well as the ductless glands. The latter part of the book treats of the nervous system and the special senses, finishing with a few words upon life and death. Short as the account necessarily is, the subject is well and clearly handled.

JOURNALS AND REVIEWS.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S. London: J. & A. Churchill. August, 1895. Pp. 174. Price 10*s.*—This part contains four articles, none having special bearing on medicine. 1. Edward T. Browne, B.A.: On the Variation of Haliclystus Octoradiatus, with a plate. 2. George Bidder: The Collæcites of Heterocœla, with a plate. 3. Henry Bury, M.A.: The Metamorphosis of Echinoderms, with seven plates. 4. Gilbert C. Bourne, M.A.: A Criticism of the Cell Theory, being an answer to Mr. Sedgwick's article on the Inadequacy of the Cellular Theory of Development. Mr. Browne found in 154 specimens of Haliclystus 120 normal and 34 abnormal specimens, the variations affecting the colleto-cystophors, the genital bands, and the number and position of the groups of tentacles. The criticism of Mr. Bourne on Mr. Sedgwick's article is ably written.

The *Journal of Comparative Pathology and Therapeutics* for the current quarter contains an article by Mr. F. Hobday entitled "Some Minor Operations in the Dog and Cat," which many of our readers who have four-footed friends dependent upon them will be interested to read. For, *pace* the rabidity of certain anti-vivisectionists and their organs, many medical men love dogs and cats and desire that they should live happy and healthy lives.



New Inventions.

PARACENTESIS NEEDLE FOR USE WITH HYPODERMIC SYRINGE.

FOR some years back I have used the paracentesis needle represented in the accompanying engraving, which has been made for me by Messrs. Arnold and Sons, London, and several medical friends who have seen it have procured similar ones for themselves. The instrument has one arm for a hypodermic syringe, and another arm to which indiarubber tubing can be attached; the central tube carries a fine needle. The advantages of the little contrivance are that a very small and not alarming instrument is used for the exploratory puncture, and that fluid if found can be removed at once. A word on the mode of use may not be amiss. The instrument having been carefully sterilised, the trocar in place, the stopcocks open, and the syringe filled with hot water, the water is driven through the instrument till only a drop or two remains in the syringe. The arm for the indiarubber tubing is now closed by the stopcock, the puncture made, the needle withdrawn, and the central stopcock closed. The couple of drops of warm water remaining in the syringe if

Digitized by Google

now pressed out will sufficiently dilute any thick fluid that may be found to allow it to flow through the needle when the piston is withdrawn. If fluid is found, the indiarubber tubing connected with an exhaust bottle can be attached at once. Should the needle get blocked, the simplest way to remove the obstruction is by injecting a little warm water

from the hypodermic syringe, which of course should have again been sterilised. This description sounds rather complicated; but a simple glance at the instrument even without any description would make clear the mode of use to anyone acquainted with its purpose.

WILLIAM R. HUGGARD, M.R.C.P. Lond.
Davos Platz, Switzerland.

AN IMPROVEMENT IN THE CONSTRUCTION OF GRATES AND STOVES.

To partially obstruct the lower part of the chimney immediately over the fire with parallel plates of zigzag iron would by most people be considered an absurdity. Yet this is practically the principle of an invention which we have recently inspected and examined, and which is claimed to consume smoke and to prevent the waste of heat up the chimney. It may be stated at once that the latter is to a very large extent ensured, since obviously, the draught being greatly reduced, the heat is not carried away in the rapid way that it is in the case of an ordinary grate, where the burning fuel is immediately underneath the wide opening of the flue. At first sight, however, it is difficult to see how such a device could possibly consume the smoke, but indirectly and to some extent it does so. The smoke issuing from the top of the chimney, serving as a flue to the stove we inspected, was quite destitute of the murkiness and sooty character of ordinary smoke, and a plug of cotton-wool placed in the flue within about 5 ft. of the fire was browned not, as it proved on testing, with tarry matters or soot, but chiefly with mineral matters containing largely oxide of iron. This was shown on treating the plug of wool with ether, which, on evaporation, yielded no tarry residue. On burning another piece of the wool the darkened portion did not disappear, but remained eventually as an indestructible brown ash. The arrangement of zigzag or corrugated metal plates, which serves in a measure to screen the smoke from its carbonaceous particles, and which, being caught in these plates, gradually burn away as the plates get hot, may be thus described:—The plates, preferably formed of cast iron, are arranged parallel to each other above the fire and under the entrance to the chimney, and are not flat, but of zigzag or corrugated form, the corrugations extending horizontally from front to back. The corrugation does not extend to the top of the plate, the upper part being left flat. A large gap is also left in the back edge of each plate, and a cast or wrought iron plate is placed at the back of the grate between the side plates fitting into this gap. A long bolt passes through the side plates and the plate at the back to secure the latter in position. A flange is provided on one side at the top of each plate. These flanges have the effect of keeping the plates at a suitable distance apart, and form also a series of narrow parallel channels, sloping slightly upwards, and serving as outlets for the products of combustion into the chimney after they have passed between the plates. The channels between the plates are narrowed as the soot accumulates, but a clear passage is always maintained, since as the plates get hot the soot appears to be slowly consumed. The plates in any case can be readily brushed clean when desired. The inventor claims that the soot so deposited plays an important part in absorbing any incomplete products of combustion which eventually disappear with the soot. This we have not established. Still, we found that the smoke issuing from the fire is robbed very considerably of its blackness and murk, and the products eventually gaining outlet into the air are free from the reproach which can be justly levelled against the outpourings of the majority of chimneys in London. Analysis showed that only traces of carbonic oxide, sulphuretted hydrogen, and unburnt hydrocarbons existed in these products. The invention does not aim directly at the perfect combustion of the fuel, but rather at removing the greater part of the sooty particles in the smoke; consequently it can be applied to any grate. It would be an excellent thing if every coal fire in London had some such device attached to it, since it would tend to minimise to an important extent the blackness which befouls the air of the metropolis, and which is largely responsible for the prevalence of the detestable and unhealthy "solid" fog in the winter season.

The grate which we examined was working in a small room at the offices of Messrs. Clarke and Bracey, 64, Coleman-street, E.C.

CARSON'S "ANTI-STOOP."

THE "anti-stoop" is an appliance for preventing or curing stooping habits. It consists of two steel arms connected at the back by a cross-piece and passing up the back of the wearer to within about three or four inches of the neck, where they branch out on either side and come over the

shoulders. At the extremity of the arms are attached padded blocks, which press gently and uniformly upon the shoulders, gradually forcing them into their proper position. The parts of the body best fitted to bear pressure are the ones, and the only ones, on which the pressure falls; these parts are the centre of the back and the front of each shoulder. The excoriation and abrasion of the skin caused by the pressure and friction of straps passing under the arms are entirely avoided. Owing to the elasticity of the steel it will give way to any sudden movement of the wearer, instead of breaking or cutting into the flesh as shoulder straps do. It can be put on and adjusted by the wearer in less than three minutes, and once adjusted can be put on without assistance in almost as few seconds, there being no straps or bands to buckle at the back. It is made in sizes to fit ladies, gentlemen, and children.

Messrs. Arnold and Sons, West Smithfield, London, are the sole agents for the sale of this appliance.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 23, 1895.

IT is doubtless á disappointment to the members of the General Medical Council not to be able to meet in their new council chamber on Tuesday next. But they have every reason to believe that the hospitality of the Royal College of Physicians of London will reduce the inconvenience of such a state of matters to a minimum. We were never sanguine that the alterations would be completed in time, and unexpected causes of delay, usual in such cases, have combined to confirm our views. It does not follow that the officials of the Council are to blame, and we believe that the President has done everything that was possible in the circumstances to fulfil the original hopes and designs of the Council. In one point he is certainly right, and that is in summoning the meeting at the usual time. The functions of the Council are too grave to be postponed for slight reasons, and though there seems to be a notion abroad that there is no serious business to be transacted we do not share the feeling. Certain gentlemen were left at the last meeting in a state of suspense as to their professional position. It is right that their cases should be defined and settled. In another important case an appeal to the Council for restoration to the Register, or even for a reconsideration of the whole facts, was referred to the Solicitor of the Council and may have to be dealt with. These cases ought not on the one hand to occupy much more of the time of the Council, but they must not on the other hand be disposed of with raw haste. The character of every registered practitioner is of consequence to the medical profession, and the principles which are at stake in such cases are of still more consequence. There is some reason to fear that for the present the Council will not have the usual assistance from the Medical Defence Union in the preparation and presentation of cases. It may be remembered that at the last meeting a case broke down from the fact that the same witnesses made opposite statements when appealed to by two sets of persons. Some members of the Council reflected on the indefatigable secretary of the Medical Defence Union. The secretary declared it was impossible to prevent such things or to cope with them until they had the power to summon witnesses and submit them to cross-examination. And we learn that the society which he represents so far agrees with him as not to intend to assume a prosecuting position at the present meeting. The Council cannot well initiate prosecutions or prepare them. It cannot be both accuser and judge. Some way must be found out of this difficulty. The Medical Defence Union and the London and Counties Medical Protection Society have done admirable service in the past at great cost, and until the Public Prosecutor becomes a more palpable and effective functionary than he is at present the withdrawal of defence societies from the work of prosecution may be a serious misfortune for the profession.

The Council will be asked by the Apothecaries' Hall of Ireland to appoint Examiners in Surgery, the Royal College of Surgeons in Ireland having withdrawn from conjunction with the Hall for purposes of giving a full qualification as required by the Act of 1886. This matter is a very important one and deserves careful attention. It is known that the Conjoint Examinations in question were considered so unsatisfactory that the Council, on the motion of Sir DYCE DUCKWORTH and Mr. BRYANT, resolved to report them to the Privy Council. What result the answer of the Privy Council will have on the action of the Council remains to be seen. But the Act of 1886 gives it power, *if it see fit*, to appoint assistant examiners to enable any corporation, otherwise unable to do so, to hold a qualifying examination under the Act. At the June meeting, on the motion of Dr. MACALISTER, seconded by Dr. MCVAIL, it was resolved: "That the Examination Committee be instructed to prepare for the consideration of the Council at its next session a series of specific recommendations embodying the results set forth in the summary of their reports." The ever-growing multiplicity and complication of examinations give an additional importance to their inspection and visitation and make it incumbent on the Examination Committee to extract any lessons it can from the inspections in the interest of the candidates and of the public. It has never appeared to us that this serious and costly part of the Council's work received the measure of attention which it merits. The motion of Dr. MACALISTER, allowing as it did six months for its consideration by the Examination Committee, leads us to expect "a series of specific recommendations" that will deal closely with the whole subject of final examinations. If ever inspections are to be utilised and made instructive it must be at the end of a complete series of them, and now, consequently, is the time for any suggestions that would improve examinations as tests "of the possession of the knowledge and skill required for the efficient practice of medicine, surgery, and midwifery."

Besides these various subjects to the consideration of which the Council is committed, there will doubtless be others arising from the motions of individual members, of which we cannot know till the appearance of the programme of business. The profession will expect to hear something of the progress made in the preparation of a new Pharmacopœia. At its last meeting the British Medical Association passed resolutions requiring its council to bring before the General Medical Council various matters of interest to the profession—notably the subject of the constitution of the General Medical Council, the inadequate amount of instruction in practical midwifery required by the Scottish medical authorities, and the objections to the creation of medical, surgical, or midwifery practitioners other than those registered under the Medical Acts. The British Medical Association does not now ask the General Medical Council to move in procuring an increase in the direct representation of the profession on the Council, but gives it notice that it is about to do so. The Council has already intimated that it will consider any Bill for the amendment of the Medical Acts introduced by the Government. We think the time is favourable for asking the Government for some very much needed amendments in the Medical Acts, including some extension of the principle of direct representation. It is to be regretted

Digitized by Google

that the Council has not shown more sympathy with the principle. It has been beaten once on this subject, and it may be beaten again. But the prospect of success will depend on the sense of moderation and proportion which is shown in the demands for amendment. Be this as it may, the Council seems to be likely to be fully occupied for four or five days.

THE view, which is becoming more and more widely accepted, that the complex of symptoms—ocular, nervous, and cardio-vascular—which characterise Graves's disease depend upon perverted or excessive function of the thyroid body has not only afforded a fairly satisfactory explanation of its varied phenomena, but has likewise led to the advocacy of such a radical measure of treatment as thyroidectomy, complete or partial. Apart from the severity of this measure in comparison with the different kinds of treatment which have been based on symptomatic grounds—such as the prescription of digitalis or of belladonna, of galvanism of the sympathetic, and such like—there always remains the problem as to the natural cause of the disease. We meet with all forms of the disorder, from the comparatively mild or abortive types ("forme fruste" of MARIE) characterised by slight vaso-motor disturbances, tachycardia and tremors, and without appreciable proptosis or even obvious thyroidal swellings, to the extremely severe forms with exaggerated nervous symptoms, including mental derangement, cardiac dilatation and its results, a thyroid tumour which threatens life by compression of the air passages, and a high degree of exophthalmos. Happily these severe cases are not very common, and for them perhaps any method of treatment is justifiable. But so uncertain and indefinite is the progress of the affection that spontaneous amelioration or entire recovery may ensue, even in cases which at one time appear to be most serious. Hence there are few diseases in which the question of prognosis is more involved in difficulty, or concerning which so much difference of opinion exists. If hospital returns are alone to be relied on, it might appear that fatal cases of Graves's disease are of great rarity; that the majority of the patients, after some months' rest and hospital treatment, pass out with their symptoms relieved or practically unaltered, whilst complete recovery is as rare as, or rarer than, death. The question is essentially one which can only be solved by the collocation of facts from the large body of general practitioners. The specialist or the hospital physician, although personally seeing far more examples of the affection than any individual general practitioner, is far less well informed as to their course after they have passed from his care. The mortality statistics are, therefore, both very diverse and very indecisive, ranging from 50 to 10 per cent.

In an address on the subject lately given by Professor PIBRAM of Prague,[1] attention is drawn to these divergent opinions, the author remarking that in his own thirty years' experience he was only able to recall three deaths in hospital and one death (from diabetes) among a large number whose history had been traced for several years after they had left the hospital. In the great majority the cardinal signs of the affection gradually disappeared—a recovery which was known to have lasted for many years (in some cases even as long as twenty years) and which therefore might be regarded as complete and permanent. Moreover, his favourable results are not based upon the observation of what may be termed the milder forms, for he gives particulars of some which were of the most severe type, associated with grave signs of cardiac failure and yet eventuating in recovery. One object of Professor PIBRAM'S paper was to check the tendency to resort to such a grave measure as thyroidectomy, and it may be remarked that the attribution of the phenomena of the disorder to primary thyroid change does not *per se* call for so radical a remedy. There is no reason why under less strong measures, or simply in the natural progress of the case, the gland should not of itself pass back from the abnormal to the normal state of activity. If it be true that the thymus gland has properties antagonistic to those of the thyroid, then a comparatively simple remedy may be found which may be as potent in Graves's disease as thyroid extract is in myxœdema.

This question of prognosis in Graves's disease, upon which so much turns, seems to be one peculiarly fitted for investigation; and it might be well worth consideration by one of our medical societies whether an inquiry for the object of determining the after-history of cases could not be instituted. There are many points that require elucidation. Thus, it would be valuable to know the order of onset of the various phenomena, their relative preponderance, the degree of cardiac derangement, and the kind of complications. Then in tracing out the later lives of those who have at one time or another shown symptoms of the affection, it would be important to ascertain not merely the duration of those symptoms or the time that had elapsed since their disappearance, but the subsequent history of the patient's mental and physical health. What proportion of those persons who have had "Graves's disease" are permanently invalided—by anæmia, by cardiac enfeeblement, or by more serious disturbances? Does the liability to tachycardia entirely disappear under all circumstances? In how many cases do actual relapses take place? What proportion are subject to pulmonary disease; or is there any special proclivity to organic affections, such as tuberculosis or cancer, albuminuria or diabetes? Do any of those who have had Graves's disease in early life suffer later from atrophy of the thyroid gland and myxœdema? What, in fact, are the prospects of health and of the duration of life in one who has been the subject of this affection? There can be no doubt that as regards many, if not most, of these questions we have comparatively little definite information, and yet there must be ample material ready to hand to supply the answers if only it could be collected.

THE preparations for the Ashanti Expedition go on apace. Some of the troops, with a considerable quantity of stores and equipment, have already been embarked at Liverpool and started for the Gold Coast, and others will shortly follow. The composition of the force, as it stands at present, will be: 600 of the West India regiment, 400 of the 2nd West Yorkshire, and 200 of the composite battalion—with the

[1] Wiener Klinische Rundschau, 1895, No. 44.

Digitized by Google

addition of fifteen or sixteen hundred made up of the Houssas and local native corps, and a contingent possibly from the Royal Navy. The Houssas have the reputation of being capital soldiers, especially for bush warfare. It is a very noteworthy and fortunate circumstance that nearly all the military authorities at headquarters, from Lord WOLSELEY downwards, who have been engaged in making the preparations for the forthcoming expedition, have a knowledge of the country acquired from actual service in it during the 1873-4 campaign, and have therefore had a personal experience of what are the necessary requirements now. Sir FRANCIS SCOTT, who goes in command of the expedition, is peculiarly fitted for the post, for he is an officer of long and distinguished service with the 42nd Highlanders in the Crimea, the Indian Mutiny, and in the Ashanti War of 1874, and subsequently, since his appointment as Inspector-General of Constabulary on the Gold Coast, he has successfully conducted two little campaigns in defence of the States under the British Protectorate.

Previously to the Ashanti Expedition under Sir GARNET WOLSELEY in 1873-4, and almost up to the very time of its being undertaken, the results of our experience of campaigns in that climate had been very unfortunate and even disastrous. We can well remember the gloomy forebodings that were indulged in at the time. It was prophesied that in a campaign undertaken by white troops in that climate the force would probably perish from sickness in a futile attempt to penetrate inwards to Kumassie, and people pointed to the results of previous expeditions in corroboration of the opinions they freely expressed. But it was altogether lost sight of that such expeditions had always been undertaken at the wrong season, and that the troops had already been deteriorated in health from residence in bad and insanitary garrisons, and had been very badly provided for and equipped for service in the field; whereas a careful consideration and survey of all the facts warranted the belief that if an expedition were undertaken in, and its operations confined to, the dry and healthy season, and if proper sanitary precautions were taken and the troops were provided with fresh instead of salt provisions and properly equipped, and if the campaign were conducted with all practicable celerity, there was every prospect of its being successful. That was the view entertained and expressed in THE LANCET at that time. The "ifs" were all discounted by the arrangements that were then made, and the result is a matter of history. It was called a doctors' and engineers' war. The stations on the seaboard were relatively few and unhealthy from sanitary neglect, the soil and climate—especially of the dense bush and low-lying portions of the country—were notoriously malarious, and fevers and dysenteric affections were very prevalent. But the climate of the Gold Coast is not of the same character all the year round, and all parts of it are not equally unhealthy; in the dry season these diseases are not only much less common, but less grave. In an expedition by the Government of the Netherlands to Kwassie-Kron in 1869, for example, the troops were healthy. Anyone who cares to turn to the medical history of the Ashanti War of 1873-74 by [illegible]. D. HOME, V.C., will find a very full and graphic account of the military expeditions in the Gold Coast Protectorate of that and previous years. Sir ANTHONY HOME states that much of the loss formerly accruing to such expeditions had been due to causes quite preventable, and he adds that this consideration no doubt greatly influenced the opinion expressed by the then Director-General (Sir WILLIAM MUIR) on the sanitary prospects of the last expedition. With regard to the detailed sanitary instructions and the equipment of this expedition he says that every point connected with it had been studied with special attention to the circumstances of an exceptional kind of campaign, and untrammelled by restrictions springing from the view that what had done before might do again; and he adds that no so carefully-provided-for expedition had ever left the shores of this or of any other country. There is no reason to suppose, therefore, that anything will be lost sight of as far as sanitary considerations are concerned on the present occasion. The older expeditions, in addition to being badly organised and supplied, just got far enough into the interior to incur all the risks of the worst places without ascertaining if things were better further on.

The route from Cape Coast Castle by the River Prah is the most direct one, but the country about Accra possesses some roads, and is much more open and hilly than that in the vicinity of Cape Coast, although the route from Accra to Kumasi—a distance of about 250 miles—is a more circuitous one. The Akropong Hills are on the direct road from Accra to Kumasi, and there seems to be no reason why some of our troops should not hereafter be quartered there or in some healthy locality in the uplands, instead of occupying the unhealthy stations they do at present on the sea coast. Be this as it may, we are chiefly interested at the present moment in the medical and hygienic aspects of the forthcoming campaign. There is no animal transport in the country, and a large force of native bearers will consequently have to be organised and everything adapted with a view to facility of transport. War is costly at any time, and small wars are disproportionately so, but that will be found the most economical procedure in the end which anticipates and provides for all reasonable contingencies. There is, of course, no doubt about the malarious and unhealthy nature of the climate, and this being so we may anticipate a good deal of sickness without necessarily a corresponding rate of mortality. But what we contend is that the sickness is mostly of a preventable character. There were only eighty-one deaths from disease and loss in action in 2587 officers and men of the European force that marched to Kumasi under Sir GARNET WOLSELEY: the mortality at the end of four months after the country had been left was 3·14 per cent. of the strength disembarked. As regards diseases, malarial fevers and dysentery are those most likely to be encountered. New comers are liable to be attacked with a climatic form of fever of short duration—the so-called seasoning fever. Quinine is now supplied in the form of tabloids and can be easily carried. We may incidentally remark that the hydrochlorate is the most soluble and efficacious form of quinine. Outbreaks of small-pox occasionally occur, but small-pox is much more likely to prove dangerous to the enemy than to a well-vaccinated army. We understand that a supply of

Digitized by Google

Pasteur-Chamberland filters will be sent with the force, and, we suppose, alum for water clarifying purposes. Ample supplies of ice are absolutely essential for the sick, and, we may add, for the comfort of the healthy also. On the occasion of the last campaign a large man-of-war, the *Victor Emmanuel*, was fitted up as a hospital ship, and the late Professor PARKES said that such a floating hospital had never, he supposed, been sent out before, and he especially extolled the ingenuity, completeness, and simplicity of the plans by which all the hospital requirements had been met. A full and critical description of this vessel was published in THE LANCET of Nov. 22nd and Dec. 6th, 1873. On this occasion the Peninsular and Oriental steamer *Coromandel*, of 4499 tons and 4500 horse-power, has been selected for the purpose, and is now in the Royal Albert Dock undergoing the necessary changes to fit her for the special work in view. We may assume that some arrangement will also be made for providing some kind of base hospital and depôt on shore at which the sick and invalids coming from the front can be received, rested, and furnished with food and supplies generally pending their embarkation on board the hospital ship. Some provision will also be made, no doubt, for the periodical transport of invalids to this country, or elsewhere if deemed necessary. We do not see why some method could not be devised for supplying soldiers on the march to Kumasi with a certain amount and variety of portable food to be used in case of need and on a forced march.

Sir WILLIAM MACKINNON, the present Director-General of the Army Medical Service, was the Principal Medical Officer of the force during the latter part of the campaign and at the taking of Kumasi in 1873–74, and his experience will therefore be valuable. Surgeon-Colonel TAYLOR is going as Principal Medical Officer of the force and he will have an opportunity of comparing and contrasting the field medical arrangements in Ashanti with those of the Japanese in the late Chino-Japanese War, at which he was present, and of which he has so recently given us a graphic account. It goes without saying that one of the great secrets of administrative success in war, especially as far as the medical service is concerned, consists in the provision and arrangement of stores and supplies ready and available for use, and in the organisation and preparedness of everything at the base; and there will be time for the accomplishment of this before the force starts and the field operations commence.

FLOODS IN BRISTOL.—Owing to the recent heavy rainfall a culvert in Montpelier, Bristol, has recently burst. This has happened on several occasions, the last time being a year ago. The damage then caused was extensive, walls being demolished and household goods destroyed, for which, although legally tested, the sufferers were unable to obtain compensation. These unfortunate scenes were repeated on this occasion. A year ago the Sanitary Committee officially submitted a remedial scheme, but beyond this nothing whatever has been done. The Bristol Sanitary Authority should at once take steps in this matter, as in addition to the great destruction of property, it is stated that illness, and even death, have been caused through the effects of these inundations.

Annotations.

"Ne quid nimis."

"RETURN CASES" FROM INFECTIOUS HOSPITALS IN THE METROPOLIS.

SO-CALLED "return cases" of scarlet fever—by which are meant cases occurring in a household shortly after the return home of a patient discharged in ordinary course from an infectious hospital—have attracted much notice of late. Something more is required to explain them than want of care and precaution in discharging the patient from hospital on the one hand, or omissions in the disinfection of his clothing at the time of removal on the other. The problem is one for consideration together with wider questions of the infectiveness of scarlet fever, and at the Epidemiological Society on Nov. 15th Mr. T. W. Thompson read a very instructive paper (which is published in full in our present issue) from this point of view. In the discussion which followed, the reality and importance of these cases were hardly called into question by any of the medical superintendents or medical officers of health who took part in it. Some doubt, however, is thrown upon the frequency of occurrence of return cases by a recent report of a sub-committee of managers of the Metropolitan Asylums Board. This sub-committee applied to the several medical officers of health of the metropolitan district for information of outbreaks of illness in households after the return home of recovered patients from the Board's fever hospitals, and report that only 165 cases of alleged infection are recorded, and in many of these there is probably no connexion of the occurrence with the return of the patient. Of these 165 cases 49 occurred in 1895, 10 from 1890 to 1891, "leaving 106 cases for the two years 1893 and 1894, during which time 30,227 patients who had been suffering from scarlet fever and diphtheria were discharged from the hospitals of the Board"—giving one alleged case of infection for every 285 discharges. From the small proportion thus shown the sub-committee conclude "that there is no evidence to show that any appreciable number of patients admitted to the Board's hospitals during the past two years have contracted infection from patients previously discharged therefrom." This conclusion is reassuring, but the figures upon which it is based should be received with some caution. It will be noticed that the 30,227 discharges were cases of diphtheria as well as of scarlet fever. Now return cases of diphtheria have not been heard of in at all the same proportion as similar cases of scarlet fever, and the number of them actually reported to the sub-committee, although not stated, is probably insignificant. Obviously return cases should have been compared with discharges for each disease separately; any proportion obtained by combining the two is misleading. Again, as regards the 165 cases reported, the appendix to the report shows that these are communicated by only twenty-six out of fifty-two metropolitan medical officers of health. For the other twenty-six some, like the medical officer of health of Bethnal-green, report that a number of cases have occurred, but do not supply details; others reply that they have no evidence bearing on the subject, and where such replies as these have been received for a district the sub-committee appear to have reckoned that district as having had no return cases at all. Further, no less than 93 of the 165 cases are reported from five sanitary districts alone, and while the sub-committee appear to find an explanation of this circumstance in faulty methods of disinfection practised in some of these areas, it is difficult to discover their grounds for this conclusion when the details given in the appendix are studied. On the other hand, the way in which the

Digitized by Google

figures have been compiled gives a ready explanation of this anomalous incidence. That the frequency of return cases of infectious illness may have been somewhat exaggerated is not unlikely, and that the experience of the metropolis in regard to them would be of the greatest value is certain. The subject well deserves further investigation by the Metropolitan Asylums Board, who might entrust it with advantage to inquirers possessed of some acquaintance with statistical methods.

A "DOCTORS' WAR."

WE have despatched a special correspondent to the seat of the war, as it is clear that the success of our military operations may turn largely upon the health of the expeditionary force. That our representative himself thinks so will be gathered from a short article, which appears from his pen on page 1314, wherein he draws upon a large experience of Ashanti to give a few details as to the medical, sanitary, and hygienic precautions that should be taken by Europeans upon the West Coast of Africa.

A JUDGE ON EPIDEMIC CRIME.

THERE is no doubt that Mr. Justice Wills entered upon the Hampshire autumn assizes with feelings of the most unmitigated disgust. Nearly one-third of the cases, he said, were of "a disgusting and filthy nature." The county at the present time, he said, seemed to be infected with a sort of epidemic of indecency, and during his long experience he had never been on any circuit where there had been such an outbreak as now presented itself, except, perhaps—and the statement was of particular interest—on the first circuit after the discussion of the articles in the papers which led to the passing of the Criminal Law Amendment Act. The outbreak, he thought, might be in some measure due to the events which had lately occurred in London, and probably when they had been forgotten the epidemic might die away, and he hoped this would be the case. Apparently he could not find strong enough phrases in which to refer to one case—a most gross charge against a county magistrate and a policeman. In this case his lordship had a long correspondence to read, which he says included letters "perfectly incomparable in their depth of degradation," showing "an amount of degradation and shame which was really inconceivable." He selected the two worst letters—both written on a Sunday and intermixed with pious phrases—which he said he hoped would suffice for the jury. There is no doubt that there is a great deal of truth in Mr. Justice Wills's remarks.

THE "NEUROSES OF CULTURE" AND THEIR REMEDIES.

WHAT Carlyle calls "diseased developments" are all too certainly caused by unhealthy literature, resorted to, as it is apt to be, for vicious excitement or sensational "distraction." We lately commented on the enactment of certain Swiss cantons by which reports of suicide are excluded from their press, these reports having been found to have a contagious effect on individuals already disposed to self-destruction. The recent charge of one of our own judges in delivering sentence on two juvenile murderers pointed so far in the same direction as to convey a strongly worded *caveat* against indulgence in the literature of crime. There are, moreover, other forms of mental deterioration induced by printed matter, less deadly, indeed, but tending to disastrous results, some of which have not inaptly been described as "neuroses of culture." This was incidentally illustrated the other day in an exceedingly vivacious and instructive lecture by Mr. Frederick Harrison on "The Choice of Books"—a subject of increasing importance, as he demonstrated, to the busy man. "Evil communications," indeed, may exert their power to "corrupt" in literature as well as in life, and the lecturer was but confirming the remark of educationists like Dr. Arnold when he referred to the sinister effect of such ill-chosen company as often finds its way into the home circle from the lending library. Idle reading is the fruitful source of idle thinking, which culminates in incapacity for thought, from which a further step in the intellectual down-grade is inability to sustain attention or even collapse of the reasoning power. "Fatty degeneration of the brain" is the definition Mr. Harrison draws from the language of pathology for the commonest results of idle reading, and there is no doubt a condition of the mental instrument which corresponds to the pathological state referred to. Mr. Harrison seeks a counter agent to the idle reading he deprecates in a sound choice of books, and a steady, intelligent mastery of their contents. The suggestion is a good one, but a better seems to us practicable. Let the busy man cultivate, or even create for himself, a subject of interest apart from that of his daily employment—a subject, be it scientific, or mechanical, or artistic, to which he can turn in his leisure hours for mental distraction and exhilaration. Let him pursue this systematically with or without the aid of others also interested in the subject, and it is astonishing how quickly his familiarity with it makes it a source of solace and relief amid other cares. Biography teems with instances of men who, as "busy" as Mr. Harrison's busiest man, have in this way found time to enrich the stores of science, of literature, of art—of knowledge, indeed, in every department. It is one of the mental occupations which are "twice blest," primarily as regards the individual, secondarily as regards the outside world. Resorted to in youth, it becomes the healthy distraction of middle life and old age, till it sometimes brings to him who practises it a reward in the present and a recognition from posterity which the formal business of his life may have failed to win.

THE PECULIAR PEOPLE AND THEIR TENETS.

AN interesting case was heard by Mr. Justice Hawkins at the Essex Assizes held at Chelmsford last week. William Cable, a member of the Peculiar People, residing at Rayleigh, was charged by the National Society for the Prevention of Cruelty to Children with having wilfully neglected certain of his children in a manner likely to cause them unnecessary suffering or injury to their health. It appears that in June and July last diphtheria was prevalent at Rayleigh, and, Cable's family being attacked, four of his children died within six weeks. One of the religious tenets of this sect being that medical advice should not be sought in case of illness, no medical man was called in to attend the patients. The question for the jury to decide was whether this was wilful neglect causing unnecessary suffering to the children. The facts were not disputed, and the prosecuting counsel acknowledged that Cable did not intend to act cruelly to his children and that he bore the reputation of being a most humane man. In addressing the jury the judge said that practically everybody had agreed to give the defendant the character of a man of great respectability, great humanity, and one extremely fond of his home and children. But if the circumstances of the case were such as would have made it imperative for the defendant to call in a medical man if he had not been a member of the Peculiar sect, then the fact of his being a member of that sect would not protect him from the obligation to do that which other persons would be obliged to do. But the jury would have to consider the case without taking into consideration the views of the Peculiar People; they must deal with it as if the defendant were an ordinary labourer. The jury, after a very short deliberation, acquitted the prisoner of wilful neglect, a verdict in which the learned judge entirely concurred. The result of this trial will be looked forward to with great interest by the coroners and

Digitized by Google

medical officers of health throughout the county, since this peculiar tenet is the cause of numerous otherwise unnecessary inquests, and on many occasions infectious diseases have been spread owing to persons of this sect who had charge of sufferers being ignorant as to the true nature of the illness. Diphtheria is regarded as simple sore-throat or mumps, scarlet fever as a "bilious attack" or German measles, and the medical officer to the Maldon rural district council, during a recent epidemic of typhoid fever, found one of these "people" suffering from this disease complicated with pneumonia, who was said to have "one of his usual attacks of bronchitis." As it is usually impossible to prove that the true nature of the disease is known to the sufferer or those in charge of him, prosecutions under the Notification of Infectious Diseases Act are futile, and such cases as the above may escape detection and serve as foci for epidemics. If it be legal to allow people to die without obtaining medical treatment, such a death should at least be illegal unless a medical man has been called in to ascertain during life the true nature of the disease. The Notification of Infectious Diseases Act undoubtedly requires amending, and a penalty should follow for neglect of notification when it can be proved that reasonable means have not been taken to ascertain the true nature of the disease. The Peculiar People are, no doubt, in their way a simple and God-fearing people, but this should be no excuse for permitting them to spread infectious diseases amongst the general community.

MR. HERBERT SPENCER ON LORD SALISBURY.

IN the *Nineteenth Century* for November Mr. Herbert Spencer takes Lord Salisbury to task for his address as President of the British Association for 1894. In that address, as our readers will remember, Lord Salisbury criticised unfavourably the doctrine of evolution, and especially the theory of natural selection. Mr. Spencer thinks the Premier confuses these two ideas and fails to recognise that even if the influence of natural selection could be disproved the doctrine of organic evolution would remain standing on other evidence. "Whether it were shown that natural selection is inoperative, or whether it were shown that though a partial cause it is inadequate to explain all the facts (the inheritance of functionally wrought modifications being a coöperative cause), or whether it were shown that no cause hitherto alleged is adequate—the general doctrine that organisms of all kinds have arisen by the continual superposing of modifications upon modifications would maintain its place, though it would not be fortified so strongly. Lord Salisbury, however, in common with the immense majority of men, assumes that the hypothesis of organic evolution must stand or fall with its alleged causal agencies." In reply to Lord Salisbury's objection that "no man or succession of men have ever observed the whole process [i.e., of natural selection] in any single case, and certainly no man has recorded the observation," Mr. Spencer points out that the alternative hypothesis—viz., special creation—is equally destitute of direct proof. "Supposing the two hypotheses—special creation and evolution by natural selection—are to be tested by the directly observed facts assigned in their support, then, if the hypothesis of evolution by natural selection is to be rejected because there are no directly observed facts which prove it, the hypothesis of special creation must be rejected for the same reason. Nobody has seen a species evolved and nobody has seen a species created." The fact is, that when once we have clearly realised what is meant by the theory of the evolution of species, the demand that anyone should have directly observed the process is an absurdity. Such an observation is *ex hypothesi* impossible. The case between the two rival hypotheses of evolution and special creation is, however, very different, according to Mr. Spencer, when we look at the indirect evidence. The more the earth's strata are examined the more they testify that organic forms have arisen by modifications upon modifications. It has been shown that the bird type is derived by intermediate forms from the reptile type. The four-toed Orohippus of the eocene strata leads by easily recognised gradations of Mesohippus, Miohippus, Protohippus, and Pliohippus to the modern horse. Fossils reveal a general law of great importance—viz., that early types of creatures in any class display the commonest or most general traits of structure, and that later types of the same class are more specialised. The facts of classification favour the evolutionary hypothesis. The relations of classes, sub-classes, cohorts, orders, genera, species, and varieties are intelligible only on the assumption of a common descent. The facts of the distribution of animals in space point in the same direction. In various regions there are alliances between the present fauna and the past fauna found fossil; though different, they are near akin. "The fact that in Australia, long cut off from the other continents, all the indigenous mammals are of the implacental type and that the fossil mammals found there are also exclusively implacental, illustrates these connexions very closely." Finally, there are the wonderful confirmations of evolution afforded by embryology. "Von Baer found that in its earliest stage every organism has the greatest number of characters in common with all other organisms in their earliest stages; that at a stage somewhat later its structure is like the structures displayed at corresponding phases by a less extensive multitude of organisms; that at each subsequent stage traits are acquired which successively distinguish the developing embryo from groups of embryos that it previously resembled, thus step by step diminishing the class of embryos which it still resembles; and that thus the class of similar forms is finally narrowed to the species of which it is a member." It is for opponents of evolution to suggest any explanation of these remarkable facts comparable in simplicity and probability to the doctrine of evolution. Mr. Spencer protests against Lord Salisbury's apparent assumption that evolution is concerned only with animals and plants, remarking that "a doctrine which alleges evolution for the animate and assumes creation of the inanimate world is absurd. Evolution, if alleged at all, must be alleged as coextensive with all existence, save that which is undergoing the reverse process of dissolution." The doctrine of evolution "has for its subject-matter the entire cosmic process, from nebular condensation down to the development of picture records into written language, or the formation of local dialects, and its general result is to show that all the minor transformations in their infinite varieties are parts of one vast transformation, and display throughout the same law and cause—that the infinite and the eternal energy has manifested itself everywhere and always in modes unlike in results but ever like in principle."

DEFECTIVE HEARING IN SCHOOL CHILDREN.

DR. WEHMER, in an admirable work on school hygiene recently published, expresses his conviction that while defects of vision among children in schools have attracted much attention of late, those of hearing have not received nearly so much as they deserve. Weil found 35 per cent. of the pupils in the schools in Stuttgart, and Moure 17 per cent. of those at Bordeaux more or less deaf in one or both ears. The degree of deafness is very easily determined by requiring the child to repeat words uttered at a measured distance in a quiet room, and unilateral deafness by closing one or other ear with the finger. Much will, of course, depend on the clearness of articulation

Digitized by Google

and the pitch, loudness, and volume of the speaker's voice; but Dr. Wehmer considers that words spoken in a man's ordinary conversational tone should be recognised without difficulty by anyone whose hearing is normal at a distance of fifteen to twenty metres—say, sixty feet. Any child whose hearing is defective or doubtful should be examined by a medical expert as to the state, not only of the ears, but also of the tonsils and naso-pharynx. Those suffering from chronic catarrhs or adenoid hypertrophies of the naso-pharynx may be recognised by their staring stupidly at the teacher while others follow the instruction intelligently, and their power of hearing varies with the weather. Their infirmity is often mistaken for mental deficiency or culpable inattention; and while diseases of the ear itself if neglected may lead to permanent and total deafness, or even to fatal meningitis, those of the naso-pharynx render the child specially susceptible to the infection of diphtheria, and in the opinion of some authorities tend to produce the enfeebled intellect which at first they only simulate. The sooner such cases are submitted to surgical treatment the better for the children, both physically and mentally. Such children are a drag on the work of a school, and even if the ultimate consequences to themselves are less grave than those we have mentioned, they are heavily handicapped through life, growing up into comparatively useless and unsuccessful members of society. The matter is one of really national importance as regards the future of the rising generation, and furnishes an argument in favour of the appointment by the school boards of medical inspectors in their several districts, men who should be competent to detect errors of accommodation and other defects of vision and to use the laryngoscope and rhinoscope, and familiar with the early diagnosis of infectious diseases and the essentials of practical sanitation, as well as with the methods of anthropometry. It is scarcely possible to overrate the scientific and social results that might be achieved by such systematic observations.

THE WATER-SUPPLY OF BRIGHTON.

FOR years past Brighton has held its own amongst the other large towns in the United Kingdom, and it will not be for the want of attention on the part of the corporation if the town does not continue to hold such a satisfactory position in the future. The *raison d'être* is, it is well known, to be found in its excellent sanitation and water-supplies. It is with regard to the latter that we wish to call attention at the present moment. By leaps and bounds Brighton is growing into a town of enormous size, and at no distant date another source of water-supply will be needed for it and the district within the corporation limits. Very wisely, the corporation have not waited till the want of an additional supply stares them in the face, they having on Thursday, the 7th inst., agreed to purchase the Shoreham and District Waterworks Company's undertaking. The source of this company's supply is a very large spring within a stone's-throw of the town of Shoreham, which is five miles only westward of Brighton. Simple everyday experiments made by Dr. Fuller of Shoreham led to the formation of the company in the year 1870. After a few years Dr. Fuller became chairman of the directors, which office he holds at the present time. For the first five years no dividend was paid at all, but from 1876 it has been a commercial success. In 1887 the full statutory dividend of 10 per cent. was paid, and this has been continued ever since, a feat due in a great measure to the admirable tact displayed by Dr. Fuller and his co-directors. The mere fact that a great town like Brighton has acquired the undertaking is more than sufficient proof that the water is of the very best and the supply abundant. Bearing in mind statements made in the House of Commons in 1878, it is a somewhat strange coincidence that Brighton has now acquired the Shoreham spring as a reserve source of supply. A private company applied for statutory powers to supply a portion of the Shoreham company's district. The Shoreham company naturally opposed this, and won the day. Dr. Fuller was a witness before the Select Committee on Private Bills, and in the course of a lengthy cross-examination by the counsel for the private company Dr. Fuller remarked that the spring was sufficient to supply the whole of Brighton. Questioned as to the abundance of the supply, the answers of Dr. Fuller led counsel to ask: "Do you draw your water from the sea, then?" "We draw our water from something which is equivalent to the sea," was Dr. Fuller's reply, "a large underground sea of fresh water." An eminent engineer at that time, also a witness for the Shoreham company, after examining the spring, said, "Well, there's enough here to supply Brighton." The total sum the council have agreed to pay for the undertaking is £56,700, and the directors have consented to receive this amount in Brighton Corporation Stock amounting to £47,250, representing at a quotation of 120 per cent. a cash equivalent of £56,700. In other words, the shareholders will receive exactly the same from the Corporation Stock as they are receiving now from the company. The cost to Brighton ratepayers will be nothing, inasmuch as the income of the company will pay the interest upon the purchase money. With its existing sources, added to which is the spring at Shoreham, Brighton should have no fear as regards its water-supply for years to come.

THE DISINFECTION OF PUBLIC CONVEYANCES

A CASE which is not without interest to the medical profession as a whole was heard at Westminster before Mr. Shell in the early part of this week. A medical man was summoned by the driver of a hansom cab for the recovery of £1 for loss consequent upon his vehicle having to undergo disinfection in accordance with the provisions of the Public Health Act. The facts in connexion with the case appear to be as follows. A child was taken by the mother to the Chelsea and Brompton Dispensary, Sloane-square, and was seen by Mr. J. J. Marsh, who diagnosed diphtheria and filled in a notification form to that effect, at the same time telling the mother to take the child home at once and to leave the notification form at the Chelsea town hall on the way. At the woman's request Mr. Marsh instructed the porter of the institution to call a cab, and, without being informed from what the child was suffering, the cabman was told by the porter to drive his fare to the town-hall. Here the party encountered the officials of the Chelsea vestry, who forthwith, with commendable vigilance, took the number of the cab and instructed the cabman to return there after depositing his fare, inasmuch as the child was suffering from diphtheria and the cab would have to be detained for disinfection. It must be related here that a statement to the effect that the mother tendered the cabman his fare was not challenged. As a consequence of the detention of the cab the driver lost two days' work, and he elected to take proceedings against Mr. Marsh for compensation. Why he did this is not quite clear, save that he appears to have considered the gentleman in question best able to bear the brunt of the expense. Mr. Marsh fought the action on purely public grounds, submitting that it would be a serious thing for medical men generally if a kind action in having a cab called for a patient should render them liable to such charges as this. The magistrate, having heard the case, was naturally satisfied that Mr. Marsh was not liable, but out of pity for the cabman intimated that possibly the case might be one for the court to relieve; and it should be stated that Mr. Marsh, having obtained the decision, generously offered to compensate the cabman. Doubtless, therefore, the driver

Digitized by Google

will not suffer, but it appears to us that Section 70 of the Public Health (London) Act might have something to say in the matter, and it is on the whole to be regretted that either an ambulance was not sent for or the woman was not told the serious penalties which she incurred by riding with an infected child in a public conveyance. We wonder what conveyance was used on the journey to the dispensary. The difficulty in cases such as these is as to where an infected person is to be housed prior to the arrival of an ambulance.

ACCIDENT INSURANCE FOR WOMEN.

So long as woman led the comparatively inactive life which until recent years custom imposed upon her, the insurance against accident of females, except in special or rare cases, was not called for to any extent. To neglect the precaution was venial. But in these days of feminine activity, when the sight of a woman alighting from a moving omnibus or riding *à l'homme* along the crowded thoroughfares on a bicycle is common, it is not surprising that the National Accident Insurance Company should have added to their tables one relating to the accidents likely to befall the gentle sex. This table, which includes the zymotic diseases, provides for accidents resulting in death, permanent or temporary total disablement, and the loss of the various members of the body, a special table being provided for hazardous occupations. Time was when woman was content to be the tutelar deity of the household, but *nous avons changé tout cela*, the female spirit yearns for equality with the male; is ever, indeed, striving to eclipse him, and not without success in some directions. Under these circumstances women stand the same risks of accident as men, and their addition to the tables of an insurance company is a manifestation of the spirit of the times.

ADULTERATION OF DRUGS.

THREE druggists have been charged at the instance of the Islington Vestry, before Mr. Bros of the North London Police-court with selling unguentum hydrargyri not containing the full amount of mercury. The deficiency was in one case 66·2 per cent., in another 11·3 per cent., and in the third 13·3 per cent. In the first case, where the deficiency was so great, the druggist defended himself curiously. He said druggists were to use their discretion—that was the reason they pass examinations. Unguentum hydrargyri, according to him, is only used as a basis for other articles. Druggists as a rule sell the weak ointment, which in the older pharmacopœias was called unguentum hydrargyri mitius. In the third case the ointment supplied was a mixture composed partly of some on hand and partly of some got from a neighbour. This neighbour was in turn asked for the same ointment, and had to apply to a third neighbour, who it was said had procured it from a wholesale druggist. Mr. Harris, the medical officer of health, would not acknowledge that the ointment was but rarely supplied by druggists. He said surgeons frequently employed unguentum hydrargyri for adults where mercury could not be given internally. One of the defendants had learnt from Mr. Martindale that in 25,000 prescriptions it had been mentioned only thirteen times in the United Kingdom and thirty times in the colonies. In the first and the third cases Mr. Bros considered the druggists had given an ointment with less than the proper amount of mercury, and required them to pay the costs, 12*s*. The second druggist, or rather his assistant, had sent out for the preparation, and that was all he could do. The ointment was not of full strength, but it was no fault of his. Perhaps the magistrate was right in letting the druggists off easily. The latter do not seem to have acted dishonestly. The theory of discretion is not applicable here. The druggist should have supplied what was prescribed. There is but one unguentum hydrargyri in the Pharmacopœia, and a medical man's prescription covered the druggist's responsibility. In the other two instances the ointment was not of the full strength, and it is unsatisfactory that the real culprit has not been ascertained. Possibly the wholesale druggist was to blame. On the face of it he was so. But nothing is proved. It would be well for the sanitary authorities to give a little attention to their preparations as well as to those of retail druggists.

COLSTON DAY IN BRISTOL.

ON Nov. 13th the usual Colston anniversary was observed in Bristol. The celebration this year was of more than common interest owing to a statue of Colston being unveiled by the Mayor. The Colston Hall, the Colston Hospital Schools, the window in the Cathedral, and now the statue all serve to keep the memory of Bristol's greatest philanthropist before the citizens. In the evening the members of the various Colston societies held their annual dinner; the collection made afterwards for the various charities amounted to £3375, being in excess of the sum received last year.

SANITATION IN SUSSEX.

ON Oct. 22nd the quarterly meeting of the sanitary committee of the East Sussex district council was held, when Dr. Leonard Wilde, D.P.H., &c., was appointed consulting medical officer to the committee at a salary of £105 per annum and travelling expenses. The appointment is for one year. At a meeting of the council held on Nov. 12th the decision of the committee was confirmed. Mr. Henriques referred to the assistance which Mr. Edgar Crookshank had afforded the committee in their selection of a candidate. We are glad to see this recognition of Mr. Crookshank's help, more especially as it affords one more instance of how valuable it is for deliberative and executive bodies concerned with the well-being of the people to number a medical man among their members.

INFANTILE PALSIES.

IN a recent number of the *Neurologisches Centralblatt* there appeared an abstract of an interesting paper by Dr. Muratoff, the original of which was published in the *Deutsche Zeitschrift für Nervenheilkunde*. Six cases of diplegia in children were observed, in two of which death took place. In one of the two the clinical condition comprised idiocy, weakness of all four extremities, and spastic and athetoid movements, with contracture and atrophy of the right upper extremity. In the brain there was found after death widespread destruction of the central convolutions and the temporal region, while the frontal and occipital regions remained unaffected. In the cervical region of the cord there was atrophy of the cells of the anterior horns, especially on the right side, and there was descending degeneration in the right pyramidal tract in the dorsal and lumbar cord. The second case was that of a microcephalic idiot with complete paralysis of all four limbs. At the necropsy there was found atrophy of both central convolutions and of the paracentral lobule on both sides, and microscopical examination of these parts showed complete disappearance of the cells. There was also in the spinal cord a simple atrophy of the pyramidal tracts without degenerative changes. Whilst in the first case, besides the symptoms of paralysis, there was also evidence of gross irritation, due no doubt to the destructive inflammatory process, in the second case there was an obsolete inflammatory process, with consequent atrophy of the central convolutions and simple atrophy of the conducting fibres, the whole to be regarded as probably the result of a developmental

Digitized by Google

defect. Dr. Muratoff concludes that (1) in spite of the similarity of clinical appearances the various forms of diplegia in children may be the result of different pathological processes; (2) the congenital form is the result of meningeal hæmorrhage and consequent atrophy of the central convulsions (the secondary changes in the pyramidal tracts are probably simple, not inflammatory, but depending upon interference with development); (3) in acquired forms the secondary degeneration is probably the result of a destructive lesion; and (4) a sub-division of the various cases of diplegia is necessary, such a classification being required as will take account of physiological and pathological changes.

THE ORIGIN OF HOSPITALS.

A CORRESPONDENT writes:—"Lately in a local paper a discussion has been raised as to the date of the origin of hospitals, and correspondents have settled the point to their own satisfaction in more ways than one. As a matter of fact the point is involved in obscurity. It is doubtful whether before the Christian era there were hospitals such as existed after. The evidence in favour of the existence of establishments for the sick amongst the Greeks is small, although Suidas mentions νοσοκομεῖον (hospital); but as the word itself does not appear until the fourth century A.D. it does not add much weight to the contention that they were in vogue before Christianity, and it seems likely that the institutions before then more partook of the nature of convalescent homes. The Romans had a valetudinarium for sick soldiers, and there is no room for doubt that the Romans possessed a medical staff, as evidenced by monuments found in Britain. But, as a matter of fact, one of the first hospitals of which anything is really known was that founded by Gallus in Cæsarea 370–80 A.D., and about the same time one was built at Rome by Fabiola. The origin of hospitals as they are now is certainly monastic. As the monks were the pioneers and patrons of arts and sciences, so they were in the founding of institutions for the sick. Every monastery had its infirmary, as every monastery had its school. The first distinct record of a hospital in England is mentioned in the life of Lanfranc, Archbishop of Canterbury, who in 1080 founded one, a part of which was set apart for leprosy and the remainder for general diseases. The hospitals remained in the hands of the monks until the Reformation, when they went the way of the rest of the monastic establishments and passed for the most part into the hands of laymen, their revenues being taken away. It may be said that several of the existing London hospitals owe their foundation to the zeal of the monks, notably St. Bartholomew's and St. Thomas's."

THE PENALTY OF INSANITATION.

A FARMER named Henry Winstanley of Ravenhead Farm, near St. Helens, was summoned to the St. Helens Police-court on Nov. 12th for failing to furnish the authorities with the names and addresses of all his customers, as infectious disease had been attributed to milk supplied by him. The town clerk prosecuted, and the defendant was represented by his solicitor. This summons was withdrawn, as the defendant in the meantime had supplied the list requested; but there was another summons charging him with keeping swine in a cowshed used by him for keeping cows in. The medical officer of health had visited the premises and found pigs and cows kept in the same shippon, contrary to the provisions of the Milkshops Order. The premises generally were in a filthy condition, and that, coupled with the notifications, made it clear that in all probability typhoid fever was being spread by the defendant. The town clerk stated that under ordinary circumstances he should have asked the bench to mark their sense of the very serious character of the offence by imposing the maximum penalty, but since the previous Friday a much heavier penalty had fallen upon the man than the magistrates could have inflicted—he himself was suffering from typhoid fever. The bench, owing to the circumstances, allowed the summons to be withdrawn, the defendant's solicitor undertaking on his behalf that the offences should not be repeated. It is useless for us to enlarge on the enormity of the offences here charged, because it has been proved over and over again that the milk-supply is a common source of the diffusion of typhoid fever and scarlet fever. Cases similar to these do, however, show how necessary it is for sanitary authorities to jealously watch the supply of milk to towns and enforce by all the means in their power the law which enables them to punish those who wilfully or carelessly transgress the sanitary laws.

THE BLOOD IN CHRONIC DISEASES OF THE STOMACH.

AMONGST the several diagnostic criteria serving to differentiate chronic ulcer of the stomach from cancer of that viscus may perhaps be reckoned the results of examination of the blood, although there are cases of the former class which apparently exhibit as profound a degree of anæmic cachexia as does malignant disease. Dr. Blindermann[1] is, however, convinced that hæmatological examination suffices to establish a difference, and publishes the results of a certain number of observations he has made in each class of cases. He concludes that it is possible by this means to differentiate between cancer and other chronic diseases of the stomach, including chronic catarrh, ulcer, and gastrectasis, although he admits that in the case of ulcer some exceptions do occur. One main difference is that in the case of cancer the hæmoglobin diminishes progressively, whereas in ulcer the rapid loss in the amount ensuing on hæmatemesis is soon regained. The exceptions to this rule are to be found in those cases of gastric ulcer in which, as Rosenstein has shown, pernicious anæmia develops, and where there also occurs diminution in the number of red corpuscles as well as the appearance of poikilocytes, microcytes, and macrocytes. Chronic gastric catarrhs, with marked dilatation, cause no manifest change in the composition of the blood.

EXAMINATIONS IN ANATOMY.

PROFESSOR FAWCETT of University College, Bristol, has drawn attention in our issues of Oct. 19th and to-day to the uncertain results of the first and second examinations in anatomy at the Conjoint Examining Board in England. He reiterates the strictures which we and others have so frequently and so fruitlessly made in regard to these examinations. *Viva-voce* examinations can only be fairly carried out when the examiners know the result of the written examination and have a fair amount of time for testing the knowledge of the candidate. An absolute time limit of ten minutes is absurd and often inflicts a grievous injustice on a student who would have passed if more thoroughly examined. It is also detrimental to the public interest, for often a candidate with a plausible manner passes, when a little further examination would show that his knowledge was very superficial and insufficient for the daily work of the profession. In fact, in setting only a small number of questions and in limiting the *viva-voce*, regard is given to the convenience of the examiners rather than to fair play for the candidate. The only excuse for the system of the Conjoint Board is that it is found by experience that roughly speaking, the results are in accordance

[1] Wiener Medicinische Blätter, 1895, No. 44.

Digitized by Google

with the knowledge of the candidates. No system can be so perfect as to admit of no mistakes, but one which would almost seem to be deliberately devised for making them should be altered. At the University of London the examination in anatomy is much more severe and thorough, but is much fairer to the student. More questions are set, and the *vivâ-voce* is not limited. The examiners have before them the marks of each candidate and can give a longer or a shorter time to his *vivâ-voce* as they may deem necessary. They can thus as readily examine six students in an hour as if they were confined to a ten minutes' time limit for everyone. Professor Fawcett urges an alteration in the examination in elementary anatomy. We agree with him that as now conducted it is useless and proves a hindrance rather than an assistance to the student. The amount of knowledge which is required is insufficient to occupy the student during his first winter session, and in consequence he too frequently wastes much of his time. We should prefer the abolition of this examination to its improvement; but if it be continued it requires much alteration, and on the lines suggested by Professor Fawcett. We understand that this abolition is contemplated by the Royal Colleges, and if this is decided on the subjects of study during the first year will require further alteration.

THE FRIEND OF HUMANITY—NEW VERSION.

WE have received from a correspondent to whom we give our thanks a copy of a lithographed letter sent out to publishers, signed by Edward Curtice, Managing Director of the Newspaper Exchange, &c., of which we append a copy:—

To the Editor of ————.

SIR,—Dr. Allinson, the well-known Hygienic Physician, is desirous of spreading the knowledge of the laws of health and his books. He proposes that you put in your columns each issue (weekly) *the enclosed advertisement*. In return for this he will supply you with *a popular medical article every week*. We need not enlarge on the benefits your paper will receive from this regular contribution from Dr. Allinson's well-known pen. You will find it will make old readers cling to you and also bring in a new set. The people are thirsting for this knowledge. It is well known to the Dr. that one paper—to which he has been attached for ten years—has at least 10,000 who take the paper for his articles alone. The knowledge imparted is in popular language and understood by ordinary readers, all medical terms being rendered into plain English.

We are entering into this arrangement with newspapers. ONE *in each district*. We therefore suggest you should secure our offer at once. It is only made by the Dr. because he wishes to educate the people and to save unnecessary suffering and premature deaths.

If agreeable, please sign the accompanying form and return it to us and oblige,

Yours truly, on behalf of the Union.
EDWARD CURTICE, Managing Director.

This is the "form" referred to:—

To the Managing Director of the
Newspaper Exchange and Advertisement Clearing House.
(Mr. Edward Curtice.) 359, Strand, London, W.C.

SIR,—On the undertaking you have given, the undersigned agree to insert (weekly) the advertisement of Dr. Allinson's books free of charge—the understanding being that the Doctor undertakes to supply a popular medical article for insertion in the ..... weekly. A fortnight's notice, in writing, on either side, will bring this arrangement to a close if desired.

Name .....
Title and address of newspaper .....
.....
Date ..... 189 . .....

"Dr." Allinson, with the candour and modesty so characteristic of true genius, does not attempt to disguise the commercial side of his nature. He is "desirous of spreading the knowledge of the laws of health *and his books*" (these italics are ours). We observe, though, that further on the agent says the offer "is only made by the doctor because he wishes to ..... save unnecessary suffering and premature deaths." The picture of the old readers clinging to the editor of the paper selected is eminently touching, and calculated to appeal to that large class whose ideas of sentiment and religion centre in cheap German lithographs and the pictures of the late John Martin, but it would be somewhat embarrassing. Fancy the editor of the "paper well known to the Dr." with 10,000 old readers clinging to him. It would make an admirable statuary group as a pendant to the Laocoon. "All medical terms are rendered into plain English." This is as well, for even the educated medical man would be puzzled by such terms as "Feton," "Fedicull," and "Peorlagis." "Medical Essays" (the contents bill of one volume of which we append) is, it will be seen, a comprehensive work. There are five volumes, and one volume costs 1*s.* 2*d.* It is to the advertisement of the five volumes that the lithographed letter refers:

MEDICAL ESSAYS Vol. IV.
For Postal Order for 1s. 2d.
It contains Articles on Hardening, Work and Over-work, Sugar and its Abuse, Milk as Food, The Tomato, Poultices, Quinine, Against the Knife, Arsenical Poisoning, Tonics, Against Stimulants in Disease, About Swallowing Pins and other Articles, Also Cure of Sunstroke, Dog Bites, Pains in the Back, Fedicull or Lice, Chickenpox, Synovitis or Inflammation of the Joints, Tonsilitis or Quinsy, Herpes (Tetter or Shingles), Erysipelas, Ulcer of the Stomach, Epidemic Influenza, Sciatica, Peorlagis or English Leprosy, &c.

The correspondent who sends us these interesting documents says: "It will show you how things are done." It does.

THE DANGERS OF SERVICE SUPPLIES.

THE past twelve months, as we have more than once pointed out,[1] have been somewhat remarkable in furnishing practical evidence of the unpleasant and serious consequences which may and do arise from defects in connexion with all three public service supplies—gas, water, and electricity. The risks of accident from water-supply are of course totally different from those of gas and electricity. True, a leakage of water may be sufficiently large to cause damage to property, but it is seldom likely to lead to personal injury. On the other hand, an escape of gas may be undetected for some time; and it only requires, as was exemplified in the street explosions which happened in the electric main boxes about this time last year, a discharge of electricity—i.e., the production of a spark—to determine an explosion. At an inquiry into the causes of these explosions the gas officials said they were due to the overheating of the electric mains, which produced inflammable gas from the insulating material and afterwards an explosion. The electrical companies declared it to be due to defects in the gas mains. There was no question of electricity having any share in the disastrous gas explosion which occurred in the Strand a few weeks ago. In this case it would appear that the water service was the seat of the mischief. From the evidence of expert witnesses at the inquest on the body of fireman Sprague last Monday it seems clear that the soil under the gas main had been washed away by a leakage of water, so that the gas main after a time formed a bridge over a gap—a condition of things which must have exposed it to severe strain, especially at the joints. The jury could not attribute blame or negligence to any person, and their verdict was "Accidental death." Service supplies are a necessity of modern existence which are bound to involve risks of a degree in accordance with the nature of the thing supplied. The origin of the mischief in the instances just quoted was the same, and may be summed up in one word—leakage. It is obviously desirable, therefore, that every conceivable precaution should be made to obviate such defects, but we imagine that those we trust for a supply of water, electricity, or gas would, in their own interests, take every precaution to avoid leakage and to prevent waste.

EXCREMENT CONSERVATION AND ENTERIC FEVER IN SHEFFIELD.

Dr. HARVEY LITTLEJOHN, the medical officer of health of Sheffield, has recently presented to the health committee

[1] THE LANCET, Nov. 2nd, 1895.

Digitized by Google

of the City Council a special report upon the prevalence of enteric fever in the district. Apparently there has been some misunderstanding upon the subject, and the committee have felt it desirable to publish Dr. Littlejohn's report. Enteric fever, it is pointed out, is unfortunately always with the people of Sheffield, and since the adoption of notification in November, 1890, no month has passed without some cases being reported. Dr. Littlejohn points out that this disease has its autumnal rise in Sheffield as elsewhere, and that this rise may in some cases be early in the autumn, in others late; and that, therefore, a rise such as is at present being experienced is not altogether an unexpected event. As an illustration of the point in question the notification returns for each month of the last five years are published in the report, the total annual figures being as follows: 354, 197, 452, 347, and 382 (up to Nov. 14th, 1895). Having thus explained to the public some points in the natural history of enteric fever, Dr. Littlejohn rightly observes that the fact of this autumnal prevalence is no argument against every endeavour being made to limit the spread of the disease in Sheffield, and he then passes on to consider the causes of its incidence on the district. Milk and water as factors in the Sheffield causation are exonerated, and Dr. Littlejohn is only able to offer one explanation of the prevalence of the disease, an explanation which he has frequently urged before—i.e., the present system of refuse and excrement disposal. The offensive and insanitary condition of the privy-middens, which fosters the accumulation of filth and tends to the pollution of the soil, is, Dr. Littlejohn considers, the chief factor in the spread of enteric fever in Sheffield. In his annual report for 1893 he went fully into the question of the connexion between privy-middens and enteric fever, and he showed the frequency with which cases recurred in certain parts of the town and also in yards with privy-middens used in common, and he now states that subsequent experience has confirmed the conclusion he then formed. The risk that these privy-middens involves form, it is pointed out, a strong additional reason for the removal of cases of enteric fever to hospital, and in this connexion reference is made to the increased chances of recovery which patients isolated in hospital possess as compared with those treated at home. We trust that the Sheffield city council will not fail to take action on Dr. Littlejohn's report.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund will be held at the Mansion House on Monday, 25th inst., at 3 P.M. The principal business will be:—To determine the report of the Council for the year 1895 and to order its publication; to revise the list of the Council for 1896; to order the convening of the next annual general meeting of constituents, and to consider what day of 1896 shall be recommended to the constituents for next Hospital Sunday.

HIS ROYAL HIGHNESS THE DUKE OF CAMBRIDGE presided at a dinner in aid of the Building Fund of the Royal Hospital, Richmond, on Monday last, at the Star and Garter Hotel, Richmond Hill. £1500 being required to complete the extensions, Mr. George C. Rowland, the secretary, submitted to His Royal Highness a list of donations amounting to £1000, whereupon Mr. Andrew Pears rose and offered the remaining sum of £500.

WE are informed by the secretary of the New Decimal Association that the metric system will be introduced into the new edition of the British Pharmacopœia. This is an important advance in the direction of the general adoption of metric weights and measures in this country, which step, it will be remembered, was recently recommended by a Select Committee of the House of Commons.

IN furtherance of a decision of the council of the Royal Medical and Chirurgical Society to devote one or more evenings in each session to a discussion of some subject of special interest, it has been arranged to hold a discussion next Tuesday upon the Possibilities as to Latency of Parasitic Germs or Specific Poisons in Animal Tissues, as in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, &c. The President, Mr. Hutchinson, will open and define the scope and aims of the discussion, Dr. Washbourn will introduce the Bacteriological Aspect of Latency, Dr. Kingston Fowler will speak on Tuberculosis, Dr. Abraham on Leprosy, and Mr. Ernest Lane on Syphilis. It is anticipated that a discussion of much practical interest will follow.

THE deputation of the delegates of the institutions interested in the formation of a new Teaching University for London will be received by the Duke of Devonshire, Lord President of the Council, on Thursday, Nov. 28th, at 12 noon.

MR. ARTHUR DACRE, the well-known actor, whose death under very sad circumstances has been recently reported, was at one time a practising member of the medical profession.

THE annual dinner of the Harveian Society of London will be held at the Café Monico on Thursday, Nov. 28th, when the President, Sir John Williams, Bart., will be in the chair.

DR. JAMES GEMMELL, Dunoon, has been appointed an Honorary Sheriff-substitute of Argyllshire.

THE CLIMATE OF ASHANTI.

(BY OUR SPECIAL WAR CORRESPONDENT.)

AS we are just now entering upon a new little war in Ashanti, and as the operations connected therewith are to be carried out at, or at any rate adjacent to, the coast-line of the Bight of Benin, between the parallels of 6 and 8 N. lat., long. 0 E., and therefore not far removed from the equator, it will be just as well to remind the readers of THE LANCET of a few peculiarities of the climatic conditions under which our European officers and men will be called upon to live, and possibly fight against, the warriors of the defiant African chieftain.

Now to say that the coast-line of this Bight is the "White Man's Grave" is as exaggerated and erroneous as to affirm that in this expedition little or no risk whatever to health or life is involved. A great deal must depend upon circumstances and how far precautionary measures are taken to prevent and check diseases in the pestilential regions. On the West Coast of Africa there are two distinct seasons—a wet and dry one. The former commences in April and lasts until the end of October, when the latter (the dry season) sets in. During June and July the rains are continuous and very heavy, accompanied by thunderstorms and violent tornadoes, the mean temperature at this season being 80° F. in the shade, and that of the water 79°. At the commencement of the dry or summer season the rains gradually abate and the weather is fine during the greater portion of the day; but dense, heavy fogs are experienced in the mornings and evenings, the temperature then rising to a mean of 82° in the shade, while that of the water will nearly touch the same point. One curious fact in connexion with this subject is that the temperature of shallow and deep water varies considerably—i.e., the temperature of the sea in shoal water will be found to be only 75·5°, while an instrument plunged into it a few miles out will register as high as 81°, showing a difference of 5·5° between them. The specific gravity of the sea at a depth of about three fathoms has been found to be about 1002. It is impossible now to go deeply into the subject of diseases prevalent in these low- [redacted] may say that

Digitized by Google

coast fever, intermittent fever, colic, and dysentery are sure to be encountered.

For an illustration of the ordinary coast fever I subjoin a typical case taken from my note-books and written during service upon the coast some years previously:—

1 P.M. Nov. 6th: A seaman aged thirty years, of stout muscular form and phlegmatic temperament, complains of headache, dorsal pain, heat of stomach, nausea, with fulness in gastric region. Countenance anxious; tongue moist; pulse small, 84. States he has felt bad for a day or two. Temperature 102° F. 9 P.M.: Diaphoresis general over body, after medicine prescribed; bowels opened, headache relieved; pulse softer, less frequent; temperature 101°.

Following morning: Symptoms the same, tongue dry in centre, moist at edges, but he complains of pain in legs; pulse 80, soft. 9 P.M.: Rigors, with heat of skin; says he is very thirsty; restless in bed; slight strangury.

Next day, 9 A.M.: Now complains of great pain at back of head; pulse 80, soft and regular; stools dark and watery. Asks for food and has taken some tea. 9 P.M.: Idem.

Following morning, 9 A.M.: Very uneasy during past night; is oppressed; countenance pallid; tongue softer and cleaner; bowels open; temperature 102°. 10 P.M.: Countenance still more palid, but otherwise the same; urine very high coloured.

Next day, 9 A.M.: More fever and incoherent; does not feel any pain; pulse soft, 84; temperature 102°. A yellowness of both conjunctivæ has set in; very restless; temperature 104°.

From this date to the 17th, or twelve days from date of seizure, he gradually became worse, the pulse rising to 110°; the tongue was loaded, but moist; while his countenance assumed the most cadaverous hue. He died in low delirium.

From the experience gained by medical officers who know the coast well, and whose testimony can be confidently trusted, it may be inferred that it will be rather late in the day to try to cure patients out there when disease in the shape of dysentery and fever has fairly got the victims in its grip. Our professional motto ought rather to be "Semper paratus," recognising the truth of the old adage that "Prevention is better than cure." Many of the surgeons who have served on the West African Coast have learnt to their cost how prolonged and how doubtful the issue of the case is whilst a patient remains exposed to the malarial influence of the locality where he or she has contracted the disease, and how futile medicinal treatment proves in arresting the progress of the complaint. They have felt convinced at last that nothing short of a speedy removal of the patient from the coast to be placed under the invigorating influence of the south-east trade-winds at sea will ever have any effect in checking or curing the depressing ailments of those who unhappily have been attacked by the baneful climate's scourge.

If the various diseases prove so refractory to medicinal treatment, are they preventable?—that is the question which now confronts us. To a certain extent they are, and measures should therefore be taken accordingly. Some few years ago the loss of health, or even life, amongst our sailors and soldiers serving in Western Africa was out of all proportion compared with that of those serving on other stations, but, happily, conditions then existing do not now obtain. The water, food, and clothing served out to our troops are much better than they were, whilst the adoption of greater cleanliness, to say nothing of the free use of modern antiseptics, has gone a great way to ward off diseases which have decimated regiments in the past. A fairly liberal supply of fresh, pure water is always essential for the well-being of any service corps, and should be obtainable even if a distilling apparatus have to be requisitioned to provide it. Polluted water stored in casks which were left standing on deck under a blazing tropical sun did its work sooner or later in those days; and water perhaps eagerly drunk from a pestilential swamp without restraint or remonstrance from an officer by some thirsty soul was formerly a potent source of mischief, originating dysentery, the *bête noire* of this much-dreaded Bight.

Now as regards the food to be served out to the men doubtless it will be, as it was in our late Soudan campaign, excellent in quality and ample in quantity, but whilst inwardly blessing our stars that the days of weevily biscuits and tainted meat and foul water have for ever disappeared, we may dismiss the subject of food from further notice by simply reminding those who do go out that they may at times have even too much of a good thing, and by too hearty a meal of excellent meat bring on a complaint they, by eating less animal food and more vegetables or ripe fruit, might easily avoid.

The subject of dress is one that needs special notice and consideration, and it should always be as light and as easy-fitting as possible. What has to be guarded against in Africa is a sudden chill, in view of the fogs and mists that are ahead of us. The present clothing of our troops marks a distinct advance upon what it used to be. No longer are our men required to march under a blazing tropical sun with tightly buttoned-up tunics and stiff stand-up stocks compressing the venous circulation and placing the wearers in the most favourable condition for courting apoplexy or sunstroke. The marches in any coming attack will probably be undertaken between the hours of 3 and 9 A.M., after the men have partaken of an early cupful of coffee or cocoa and a mouthful or two of good biscuit. Then, too, at the midday halt, unless actually in the presence of the enemy, they may possibly be permitted to loosen their clothing, so as to give their chests a freer expansion, or even be allowed to enjoy the comforts of a brief siesta during the heat of the tropical midday sun. That will be all very well; but it should ever be remembered that as soon as the sun wanes the fog sets in, and a distinct chilliness creeps over nature and must be guarded against at all costs. Now is the time for flannels, and they ought to be put on if disease is to be avoided. The cool evening air is very refreshing, no doubt, but it is laden with mischief, as every African traveller knows. With a liberal supply of good water, avoidance of excess in eating as well as in drinking, and with great care on the part of the men not to expose their overheated bodies to any sudden chill, there is, I think, no reason why this expedition, so well equipped as regards medical officers and their requirements, should not return little the worse for campaigning in Ashanti-land.

A TEACHING UNIVERSITY FOR LONDON.

ON Wednesday, Nov. 20th, a general meeting of the teachers in the medical schools of London was held at the Examination Hall, Victoria Embankment, to consider a resolution pressing the Government to appoint a Statutory Commission to deal with the recommendation of the Gresham University Commissioners. The meeting may fairly be said to have represented, as Dr. Norman Moore happily suggested, the medical faculty of any future university in London, and consisted of a representative gathering of both experienced and quite young teachers, together with several ladies. At the commencement of the proceedings it seemed as if the members of the meeting were not altogether in harmony, for after the first resolution, subsequently unanimously agreed to, had been moved—

"That the Government be requested to introduce, at an early date, a Bill similar to Lord Playfair's London University Commission Bill, 1895, appointing a Statutory Commission to carry out the recommendations of Lord Cowper's Commission; but with an added clause giving (in accordance with precedent Acts of similar tenor) to all institutions or persons directly affected by any statute or ordinance proposed by the Statutory Commission a right of appeal to the Privy Council for the disallowance or alteration thereof, previous to such ordinance being laid before Parliament for confirmation"—

Dr. Isambard Owen pointed out that whilst the delegates of the medical schools had at their last meeting agreed to a resolution pressing the Government to appoint a statutory commission to "deal with" the recommendations of the Gresham University Commissioners, these words had only been inserted in the invitation, and that in the resolution before the meeting the words "carry out" had been substituted for "deal with." The resolution and the invitation were not in accord, for the one meant, and was intended to mean, much more than the other. Professor Curnow stated that all the signatures from King's College had been obtained under the idea that the wider signification was intended, and that this was indicated by those who had signed their approval. Professor Ramsay of University College, who said that he was largely responsible for the wording of the resolution, expressly stated that the objects aimed at by Dr. Owen and Professor Curnow were quite appreciated by the framers of the resolution, and were met by the phrase "similar to Lord Playfair's London University Commission Bill, 1895," and on

Digitized by Google

this explanation the protest was withdrawn. The following formal resolutions, on the motions of Dr. F. Payne and Dr. Mitchell Bruce, respectively, were then passed:—

"That all teachers be asked to sign the preceding resolution, as 'approved' or 'not approved,' and that the chairman be requested to forward a copy of the resolution, with the signatures obtained, to the Lord President of the Council, and other copies of the resolution to the Prime Minister and the President of the Council of Education."

"That the appointed delegates of the medical schools of London be requested to attend, with the representatives of other institutions concerned, a deputation to the Lord President of the Council, and to convey to him the wishes of this meeting as expresed in the first resolution."

A vote of thanks to the Committee of Management of the Conjoint Board for England for the use of the hall, and the usual courtesies to the chairman terminated the proceedings.

The occasion is noteworthy, as it is the first meeting of medical teachers in London which can be called a representative one, and we are glad that a unanimous resolution was passed. However much we may differ as to methods, we cordially hope that this meeting will prove an efficient stimulus in the renewed agitation on behalf of fair degrees for London medical students.

LEGISLATION FOR HABITUAL DRUNKARDS.

DEPUTATION TO THE HOME SECRETARY.

ON Friday, the 15th inst., the Home Secretary was waited upon by a deputation to urge the need for amending the law relating to habitual drunkards.

Dr. Norman Kerr, President of the Society for the Study of Inebriety, in introducing the deputation, announced the receipt of letters, approving of its object and expressing regret for their unavoidable absence, from the Duke of Westminster, Sir Richard Quain (President of the General Medical Council), Sir William Broadbent, and Dr. Long Fox (ex-President of the British Medical Association); also from the following members of Parliament: Messrs. Lees Knowles, Edmund Boulnois, and W. Johnston.

Dr. Kerr said that the solid mass of habitual drunkards, on which efforts of legislation, philanthropy, and religion had made little impression, with the increasing proportion of diseased inebriates, especially female, constituted a menace to public order. Regarding police-court inebriate offenders, it was now generally agreed that the existing procedure was a miserable failure, and neither deterred nor reformed them. Scientific students of the subject held that there was a physical as well as a moral aspect of inebriety, while the curative treatment of habitual drunkards had been recommended by no less than six State reports. Objection had been raised, on the ground of expense, to any alteration of the present system, but the money spent on the present system of imprisonment was worse than wasted. As to the non-criminal habitual drunkards, the existing Acts had done some good, but they required certain amendments. At present the habitual drunkard had to make a declaration before two justices before he could be admitted to a curative retreat. It was difficult to get the male, and still more difficult to get the female, inebriate to face such an ordeal, and one justice might be less formidable than two, or, he suggested, the declaration might be made, as in America, before a statutory commissioner, and entrance to such retreats should be facilitated. The term habitual drunkard should be so extended as to apply to persons addicted to the excessive habitual use of such narcotics as morphine, chloral, and cocaine, alcoholic drunkenness being only one form of inebriety. Another important defect of the existing Acts was that they only applied to those who could afford to pay. There were a few homes for inebriate women supported by philanthropy, but none for poor inebriate men. Provision for the curative treatment of poor inebriates of both sexes was required. As to the objection that it would be a new departure in English jurisprudence to subject to compulsory seclusion and curative treatment inebriates who had not broken the law, such an objection was fallacious, seeing that existing laws authorised analogous treatment of insanity, of which disease inebriety was practically a form. Provision could be made against any possible abuse of the power suggested, although no abuse of it had occurred in countries where it existed. Medical men did not desire to administer the proposed law, but to act under judicial authority and support the liberty of the subject.

Cardinal Vaughan said that further power was required to commit habitual drunkards to homes, where some 8 or 9 per cent. had been cured.

The Rev. Canon Duckworth, representing the Homes for Inebriates' Association, advocated fresh legislation in the direction indicated, maintaining that it would not be in advance of public opinion. Those for whom he spoke were as zealous for the liberty of the subject as anyone, but could not see why the liberty of the inveterate sot should be more respected than the welfare and liberty of his family.

Sir W. Charley, Q.C., suggested the restoration of the compulsory clauses of the Bill of 1877, the voluntary clauses of which had become law, with the result that patients who could pay had been treated in homes, the cures being many like 30 per cent. than the 8 or 9 per cent. mentioned by Cardinal Vaughan. As to the "liberty of the subject," where was it under the existing system in such a case as that of Jane Cakebread, who had been committed nearly 300 times? Magistrates should have the option of sending such cases to homes instead of to prisons.

Dr. Danford Thomas, coroner, pleaded for the proposed changes on behalf of the poor, he being a daily witness of the misery caused among them by habitual drunkards. During an experience of twenty years as coroner not a day had passed but he had held inquiry into a death due directly or indirectly to drunkenness. Nearly all the existing homes for inebriates were beyond the means of poor people, and the few that existed for poor women would not suffice to accommodate one case in a thousand requiring treatment. It was no more an interference with the liberty of the subject to place inebriates under compulsory treatment than to send cases of infectious diseases to hospitals. The cost would be covered by the saving the change would effect in the present outlay upon inebriates in workhouses, prisons, &c.

Mr. C. J. Maddison, Reformatory and Refuge Union, concurred.

The Home Secretary (Sir Matthew White Ridley), in reply, said that it did not require such an influential deputation to convince him of the importance of the question, but the difficulty of dealing with the non-criminal habitual drunkard was very great, as was shown by the reception with which the carefully drawn Bill of his predecessor in office had met. As to the analogy between the treatment of lunatics and the proposed treatment of inebriates, the former might soon recover and could be released, while it took, as he understood, twelve months or more to cure inebriates. With regard to the liberty of the subject and the remark that victims of infectious diseases were sent to hospital, he held that inebriety, although bad, was not so fatal to the community as infectious disease; but he could not ignore the reports of the committees to which reference had been made, and it would be of the greatest importance to the country if he could extend the system of curative treatment while safeguarding the liberty of the subject. He understood that some 6000 female inebriates were at present imprisoned. He quite agreed that something should be done in the case of criminal inebriates, and that it would be a saving to the country to cure them. Some of the proposals of Mr. Asquith's Bill might serve as a basis for tentative legislation. Regarding the difficult problem of the non-criminal inebriates, he would look into it and would be glad to see cured people who were a curse to society, and he favoured tentative efforts rather than heroic legislation.

Dr. Norman Kerr having thanked the right hon. baronet, the proceedings terminated.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5.30 P.M. on Nov. 13th, at 25, Grosvenor-street, W. Mr. Holmes, Vice-President, occupied the chair, in the unavoidable absence of the President, Mr. George Pollock. The minutes of the last meeting were read and confirmed. The honorary secretary (Mr. Percy Dunn) reported that, as it had been found impossible to summon the members of the Association for the annual general meeting as arranged at the

Digitized by Google

previous meeting of the committee, it had become necessary to fix a later date, and for that purpose, as well as for the preparation of the agenda to be submitted to the members, he had called the committee together. After some discussion it was agreed that a meeting of the committee should be called for Dec. 4th, and that the annual meeting should be definitely fixed for Dec. 11th, 1895.

A letter was read from Major-General Graham, secretary of the Civil Rights' Defence Committee, asking the association to appoint a representative to act on his committee, and requesting the committee of the association to receive a deputation from the Civil Rights' Defence Committee. A letter was also read from Mr. R. B. Anderson in support of the foregoing application from Major-General Graham, and containing a short statement of the main facts of his case. A resolution was passed unanimously agreeing to receive the deputation aforesaid, and the honorary secretary was instructed to write to Major-General Graham to this effect, and at the same time to state that the committee would be prepared to receive the deputation at 5.30 P.M. on Dec. 4th, at 25, Grosvenor-street.

Mr. Anderson having expressed to the honorary secretary a desire to join the association, he was proposed, seconded, and unanimously elected a member of the association. After some discussion upon Mr. Anderson's case the following resolution was agreed to: "That the committee of the Association of Fellows beg to express their warm appreciation of the action taken by the Council of the Royal College of Surgeons as representing the College in the matter of Mr. Anderson's attempt to vindicate his legal rights as a Fellow of the College. They sympathise entirely with Mr. Anderson, and intend to bring his case before the association with a view to appoint a delegate to act on their behalf on the Civil Rights' Defence Committee." The honorary secretary was instructed to forward a copy of this resolution to the secretary of the College for the purpose of its being laid before the Council at their next meeting.

With reference to the appointment of a representative of the association on the Civil Rights' Defence Committee it was decided that, as this would be a new departure, it would be advisable to defer the consideration of the subject until the annual general meeting of the association on the 11th prox.

This concluded the business of the meeting, and the committee adjourned.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Enteric Fever at Widnes, by Dr. R. BRUCE LOW.[1]—This report, which was compiled some months ago, deals with a sustained prevalence of enteric fever in the borough of Widnes. The deaths from fever for the three years ending with 1894 were 26, 32, and 24, the population being somewhat over 30,000. There occurred also during the same years the following deaths from diarrhœa and English cholera—viz., 18, 48, and 15 respectively. And, again, in the five years ending 1894, during which time there was notification of infectious diseases in the borough, there occurred 587 attacks of continued fever, 566 being returned as "enteric" or "typhoid"; there was also a tendency to increase at each autumnal season. The different parts of the borough suffered unequally, the ward known as West Bank, which is not the most densely populated, having the highest fever attack rate. The water-supply for the borough seemed excellent as regards its source, and well cared for in its distribution; the question of milk as a vehicle of infection did not arise; neither was there any evidence that sewer air had had any real share in the distribution of the disease. But when we read Dr. Low's description of the means of excrement disposal in the borough we find ample justification for the belief that this excremental disease was provided with just the means which it requires for its propagation and distribution. It is unnecessary for us to describe the midden-privy with which the bulk of the Widnes houses is provided. The diagrams attached to Dr. Low's report suffice to show not only, as he says, that "it has nothing whatever to recommend it," but that it is altogether faulty and opposed in its construction to every sanitary principle. Oddly enough, it is locally called the "modern convenience"; but it has nothing modern about it, unless, indeed, it is the production of ignorance during comparatively recent years. "In a word," writes Dr. Low, "the air round the dwellings in Widnes is habitually fouled by emanations from collections of human filth stored close to the houses under very unfavourable conditions, and the tainted atmosphere that is breathed by the inhabitants cannot fail to have an injurious effect upon them." The truth is that owing to the filthy contrivances in question Widnes was found to possess precisely the conditions such as are known everywhere and, we had hoped, by everybody "to greatly favour the diffusion of enteric fever." Happily, we learn that this system is condemned by the sanitary officials, and that efforts have for some time past been made to get rid of it. It has probably been an expensive burden thrown on Widnes, for it has had an important share in producing one of the most costly and wasteful of diseases—one that attacks the bread-winners and young adults during the period of life which is most remunerative, and it has cost the people many valuable lives. We can only hope that this lesson has now been fully learnt; but it is somewhat disheartening to find so often that English people have not yet grasped the simple fact that to accumulate large quantities of excremental filth close to houses, where it lies decomposing and fouling the air that has to be breathed, is utterly opposed, not only to decency, but also to public health.

[1] Eyre and Spottiswoode, East Harding-street, London, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis, and Co., Dublin. 1895. Price 6d.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Manchester Urban Sanitary District.—Dr. James Niven has issued his first annual report as to the health of Greater Manchester. The report relates to the year 1894, and a perusal of it is sufficient to show that the health of the largest provincial city in England is in safe keeping, and that its statistics will be turned to excellent account. The marriage-rate of Manchester has gradually declined from 24·2 per 1000 in 1871 to 16·0 in 1893, while the birth-rate has been reduced from 40·0 per 1000 in 1876 to 31·8 in 1894. Dr. Niven dwells fully in his report upon the effect these diminutions may be held to have upon the mortality-rates. The general death-rate for 1894 was but 19·8 per 1000—i.e., 3 per 1000 less than in any year since 1871. The reduction of the death-rate was more marked in the township of Manchester than in either the north or south division of the city, a fact which Dr. Niven thinks may be due in some degree to the improvement of dwelling-houses in the older parts of the city. The reduction in infantile mortality during 1894 was very remarkable, and the reduced general death-rate is due in no small degree to the diminished mortality from summer diarrhœa. The infantile mortality in 1894 was but 158·5 per 1000 births, as compared with rates of 191·7, 178·2, and 201·3 in the preceding three years. The chances of survival in Manchester of legitimate and illegitimate children is shown in the annexed table:—

Percentage of illegitimate to total births.		Proportion of deaths under one year per 1000 births.		
		Total.	Legitimate.	Illegitimate.
1891	4·23	192	184	375
1892	4·10	178	170	367
1893	3·72	201	190	498
1894	4·42	159	150	338

In connexion with the general death-rate of Manchester it is interesting to note that a far higher proportion of deaths occurred in public institutions during 1894 than ever before, and this increased tendency to resort to institutions, where care and treatment are better than at home, may have a material effect in the diminution of the general death-rate of Manchester. On comparing the mortalities of the different divisions of the city it is found that Manchester township exceeds that of South Manchester, which in its turn exceeds that of North Manchester. Although in these differences there is a general relation

Digitized by Google

between a high density of population and a high death-rate, Dr. Niven, by a very thorough analysis of the mortality of the several districts in the city, shows clearly that there are other local factors which in large part override that of density. It is this part of Dr. Niven's report which is especially worthy of careful perusal. The Manchester figures in regard to enteric fever show that this disease is not more prevalent in those districts where the summer diarrhœa incidence is high. The causes of enteric fever are, Dr. Niven considers, much more complex than those of diarrhœa. In the report before us is a table giving the death-rates of enteric fever per 1,000,000 of the population in England, London, Manchester, Prussia, and Berlin for many years past, its object being to show that Manchester has not shared in the diminished mortality from this disease which has been manifest in the other places referred to. In connexion with this question of diminished enteric fever mortality, Dr. Niven has procured statistics as to the fatality-rate of enteric fever in some of the largest fever hospitals in England and Scotland, but these fail, it appears, to show that the general diminution of the disease is to be attributed in any marked degree to improved methods of treatment. With two important matters contained in Dr. Niven's report we have already dealt—i.e., small-pox and "an occurrence of milk infection," the latter of which was contained in a special article by Dr. Niven;[1] and we can only add that the report before us contains a very able dissertation upon back-to-back houses in which the subject is treated with considerable originality. Dr. Niven devotes himself in the main to a consideration of the fallacies which may attend conclusions on back-to-back house figures, and after a very thorough analysis of the figures and facts relating to Manchester he agrees with the general results obtained by Dr. Tatham and Mr. Herbert Jones—i.e., "that back-to-back houses by their mode of arrangement produce a direct injury to health which, however, so far as death-rates are concerned, is most manifest in early life and at advanced ages." These pages of Dr. Niven's report will be read with much interest by all medical officers of health, and, in conclusion, we heartily congratulate him upon his first annual report for the city of Manchester.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6291 births and 3876 deaths were registered during the week ending Nov. 16th. The annual rate of mortality in these towns, which had increased in the four preceding weeks from 19·1 to 22·1 per 1000, declined again last week to 19·1. In London the rate was 17·9 per 1000, while it averaged 19·9 in the thirty-two provincial towns. The lowest rates in these towns were 10·0 in Huddersfield, 12·2 in Brighton, 13·0 in Derby, 13·2 in Leicester, and 14·6 in Plymouth; the highest rates were 23·7 in Wolverhampton, 25·0 in Salford, 26·2 in Bolton, 30·8 in Liverpool, and 36·4 in Blackburn. The 3876 deaths included 522 which were referred to the principal zymotic diseases, against 590 and 606 in the two preceding weeks; of these, 163 resulted from measles, 107 from diphtheria, 83 from diarrhœa, 66 from whooping-cough, 64 from "fever" (principally enteric), 38 from scarlet fever, and 1 from small-pox. No death from any of these diseases was recorded last week in Plymouth; in the other towns they caused the lowest death-rates in Leicester, Brighton, Croydon, and Derby, and the highest rates in Liverpool, Salford, Wolverhampton, and Blackburn. The greatest mortality from measles occurred in Liverpool, Wolverhampton, Salford, Oldham, and Blackburn; from scarlet fever in Gateshead; from whooping-cough in Liverpool, Newcastle-upon-Tyne and Wolverhampton; and from "fever" in Salford, Oldham, Burnley, and Sunderland. The 107 deaths from diphtheria included 61 in London and 8 in West Ham 5 each in Wolverhampton, Birmingham, and Liverpool, and 4 each in Manchester, Salford, and Newcastle-upon-Tyne. One fatal case of small-pox was registered in West Ham, but not one in London or in any other of the thirty-three towns. There were 86 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Nov. 16th, against 114, 106, and 78 at the end of the three preceding weeks; 23 new cases were admitted during the week, against 14, 29, and 14 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2845, against 2833, 2841, and 2847 on the three preceding Saturdays; 298 new cases were admitted during the week, against 269, 215, and 349 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 366 and 447 in the two preceding weeks, declined to 340 last week, and were 84 below the corrected average. The causes of 50, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, Hull, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, and Leicester.

[1] THE LANCET, Jan. 19th, 1895.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 18·9 to 21·4 per 1000, declined again to 18·5 during the week ending Nov. 16th, and was 0·6 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·2 in Leith and 15·9 in Dundee to 22·5 in Aberdeen and 26·8 in Greenock. The 535 deaths in these towns included 18 which were referred to whooping-cough, 11 to diarrhœa, 9 to scarlet fever, 5 to measles, 5 to diphtheria, 3 to "fever," and 1 to small-pox. In all, 52 deaths resulted from these principal zymotic diseases, against 69 and 77 in the two preceding weeks. These 52 deaths were equal to an annual rate of 1·8 per 1000, which was 0·8 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased from 11 to 21 in the three preceding weeks, declined to 18 last week, of which 14 occurred in Glasgow, and 3 in Aberdeen. The 11 deaths referred to diarrhœa showed a considerable decline from those recorded in recent weeks and included 5 in Glasgow. The fatal cases of scarlet fever, which had been 10 and 11 in the two preceding weeks, declined again to 10 last week, of which 3 occurred in Glasgow and 3 in Edinburgh. The 5 deaths from measles were within one of the number in the preceding week, and included 3 in Greenock. The fatal cases of diphtheria, which had been 5 and 8 in the two preceding weeks, declined again to 5 last week, of which 2 occurred in Glasgow. The 3 deaths referred to "fever" were considerably below the number recorded in any recent week, and included 2 in Edinburgh. The fatal case of small-pox occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 136 and 173 in the two preceding weeks, declined to 134 last week, and were 21 below the number in the corresponding week of last year. The causes of 40, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·5 and 24·3 per 1000 in the two preceding weeks, further declined to 23·1 during the week ending Nov. 16th. During the past seven weeks of the current quarter the death-rate in the city has averaged 24·6 per 1000, the rate during the same period being 18·4 in London and 17·6 in Edinburgh. The 155 deaths registered in Dublin during the week under notice showed a decline of 8 from the number in the preceding week, and included 6 which were referred to the principal zymotic diseases, against numbers declining from 29 to 8 in the five preceding weeks; of these, 2 resulted from small-pox, 2 from "fever," 2 from diarrhœa, but not one from measles, scarlet fever, diphtheria, or whooping-cough. These 6 deaths were equal to an annual rate of 0·9 per 1000, the zymotic death-rate during the same period being 2·6 in London and 1·5 in Edinburgh. The deaths referred to different forms of "fever," which had been 2 and 4 in the two preceding weeks, declined again to 2 last week. The fatal cases of diarrhœa, which had declined in the five preceding weeks, from 17 to 2, were again 2 last week. The 2 fatal cases of small-pox exceeded the number recorded in any week during the current quarter. The 155 deaths in

Digitized by Google

Dublin last week included 23 of infants under one year of age, and 33 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. No deaths from violence were recorded and only one inquest case was registered; and 46, or nearly a third, of the deaths occurred in public institutions. The causes of 11, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

THE ASHANTI EXPEDITION: MOVEMENTS OF THE MEDICAL STAFF.

WE understand that the hospital ship which is now being fitted out for the Ashanti Expedition will be in the Medical Charge of Brigade-Surgeon-Lieutenant-Colonel E. Townsend, and that he will be assisted by Surgeon-Majors Porter and Dodd. Surgeon-Major Wilson and Surgeon-Captain Eckersley have received orders to embark for Cape Coast Castle on the 23rd inst. Surgeon-Major Wolseley, who is also under orders for Ashanti, will be in command of the detachment, Medical Staff Corps, and Surgeon-Captain O'Callaghan will be his second in command. Surgeon-Majors Hickman, Bartlett, and Hughes, and Surgeon-Captains Beevor, Hilliard, Josling, and Barker are also under orders to join the expedition. The Nursing Staff on board the hospital ship will consist of Nurse Gray (Acting Superintendent) and Sisters Potts and McCordy.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel John Maturin, F.R.C.S.I., to be Surgeon-Colonel, vice J. B. Hamilton, M.D. Brigade-Surgeon-Lieutenant-Colonel Charles White is placed on retired pay. Surgeon-Lieutenant-Colonel George D. N. Leake to be Brigade-Surgeon-Lieutenant-Colonel, vice J. Maturin, F.R.C.S.I. Surgeon-Lieutenant-Colonel Poole R. Gabbett to be Brigade-Surgeon-Lieutenant-Colonel, vice H. W. A. Mackinnon, D.S.O., retired.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel G. Hutcheson (Bengal) is granted the temporary rank of Surgeon-Colonel whilst officiating as Inspector-General, Civil Hospitals, North-West Provinces and Oudh, during the absence on leave of Surgeon-Colonel W. P. Warburton. Surgeon-Captain J. M. Cadell, Officiating Civil Surgeon, on completion of special duty, is to take Civil Medical Charge of the Dehra Dun District as a temporary measure.

The following officers have embarked for a tour of service in India:—Surgeon-Lieutenant-Colonel Charlesworth, Surgeon-Majors Lane, Ellis, and Donovan, Surgeon-Captain Reade, and Surgeon-Lieutenant MacMunn.

The *Army and Navy Gazette* says that a general redistribution of medical officers in India will take place now that the Chitral force is completely broken up. The British General Hospital at Cherat having closed, only the Station Hospital remains, with Surgeon-Major Saunders and Surgeon-Captains Butchell and Brogden. Surgeon-Captains Swan, Hathaway, and O'Donnell, on return from Chitral, are posted to Peshawur; Surgeon-Captains Aplin and Vost resume duty with the Civil Department, North-West Provinces. Brigade-Surgeon-Lieutenant-Colonel Anthonisz goes to Jubbulpore, Surgeon-Major Carleton to Bellary, Surgeon-Majors Roy and Adams to Neemuch, Surgeon-Captain Thurston to Bareily, Surgeon-Captain Pilcher to Lucknow, Surgeon-Captains Jameson and Tyrrell to Rawul Pindi, and Surgeon-Captain Bunn, Army Medical Service, is re-posted to Bareily."

YEOMANRY CAVALRY.

Surgeon-Captain G. R. T. Phillips to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 1st Cumberland: George Martin, gent., to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant W. Vernon resigns his commission. 2nd Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Captain J. Martin resigns his commission.

THE ASHANTI PREPARATIONS.

The daily papers have given pretty full accounts of the preparations that are being made for the Ashanti expedition, and there has been of late great activity at the War Office. Time is always an important element in a matter of this kind, and happily there has been sufficient time allowed on the present occasion to make the necessary arrangements and preparations. According to the published accounts in the *Times* and other papers of the stores and supplies these would seem to be very complete and suitable for a campaign in such a climate. Trial is to be made of Maconachie's tinned ration of mutton, vegetables, and gravy; and also of "emergency rations," consisting of chocolate and solidified beef-tea. Cocoa, chocolate, and tea will, of course, be freely supplied; and we are not, on the whole, sorry to see that there will be an issue of rum. If this be given in moderate quantities with food towards the end of the day and after marches it will be found to be beneficial and not injurious to the troops; soldiers on the march enjoy and look forward to the daily issue of a spirit ration. The provision of tobacco for soldiers in the field is also a wise and good one in our opinion. For such a climate a lighter kind of tobacco than that which the soldier uses at home is, however, desirable. The water procurable commonly contains a good deal of suspended matters and vegetable débris, and the use of alum—of which a quantity will be supplied—is to be advocated as an excellent water clarifier. As regards the *personnel*, it is understood that some twenty medical officers and about 100 men of the Army Hospital Corps have already been placed under orders, with a number of lady nurses. It is, we believe, intended that the Army Hospital Corps will be divided into three sections—one for the base and lines of communication, another for the hospital ship, and the third for service in the field with the advancing troops. The difficulty on this occasion, as on others, has not been to obtain officers, non-commissioned officers, and men of all branches of the service, for all ranks are ready enough to volunteer for this and every other campaign, but to select the requisite number out of those desirous of going.

"THE SANITARY CONDITION OF ALDERSHOT."

Under the above heading a correspondent who signs himself "E. F." writes to the *Morning Post* of Nov. 19th making some grave charges respecting a subject we have repeatedly called attention to in the columns of THE LANCET. "Two or three months ago," he says, "a young Artillery officer was sent home from Aldershot suffering from scarlet fever arising from the insanitary condition of his quarters, where the sewage came up through the boards, the excuse being that it would cost £5000 to remedy the evil. During the illness of the officers the place was examined and reported to be thrown down. You will scarcely believe that after their return to quarters the officers were again put into that unhealthy den, but such is the case. On Monday last my young friend was again sent home, sickening for typhoid fever, and now lies under the care of two doctors and two nurses. Others of his companions may be suffering in the same way. The regiment is to go to India next year. Is it to prepare them for India that they are put into fever dens?" If such a condition of things really exists at Aldershot it is certainly time that some drastic measures should be taken by the Government to free this question from the red-tapeism in which it has been too long entangled.

THE MALARIA PARASITE.

The *Times of India* of the 26th ult. contains a lengthy communication descriptive of the results of Surgeon-Lieutenant-Colonel Lawrie's observations and experimental researches on this subject. It is well known that this officer, as the result of some 200 observations made on healthy and malarial and other diseased blood, denies the existence of the plasmodium in the blood of malarial patients. While a considerable number of experiments seem to have been made on stained specimens, but little mention is made as to the results of the examination of fresh blood. But we have not yet seen any printed report of these observations, and it would, therefore, be quite premature at present to form any conclusion in regard to them.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

Lieutenant-General G. H. Moncrieff will present the prizes of this school at 7.30 P.M. at the Banqueting Hall, Crosby Hall, E.C., on Saturday, Dec. 7th. Among those who have accepted the invitation of the Staff to be present are Brigadier-General W. H. Gatacre, D.S.O., recently commanding the third brigade of the Chitral Expeditionary Force. Captain Sir Alfred Jephson, R.N., Secretary-General

Digitized by Google

of the Order of St. John of Jerusalem, and Colonel Sir Herbert Perrott, Secretary of the Order. Past and present members of the school can obtain tickets for the distribution and concert by making early application to Mr. C. J. Downer, Fairfield, Willesden-park, N.W.

THE NAVAL EXAMINATION.

The under-mentioned gentlemen who recently competed for appointments as Surgeons in the Royal Navy have been granted commissions:—

C. H. J. Robinson	2634	H. H. Gill, M.B.	2289
H. Huskinson, M.B.	2579	W. D. Adams, M.A., M.B. ...	2244
E. S. Tuck	2548	W. R. Trythall	2233
H. G. T. Major	2529	E. G. E. O'Leary	2188
M. P. Jones	2372	J. C. Rowan, M.B.	2155
A. W. B. Livesay, M.B. ...	2344	R. A. Ross, M.B.	2042

THE CLARENCE SMITH CASE.

We learn from the Indian papers that the commission appointed to investigate the facts connected with the case of Surgeon-Major Clarence Smith of the Indian Medical Service, to which, it will be remembered, we have already referred, have terminated their inquiry, but the result has not been promulgated.

We are informed by a correspondent that the common iliac artery was tied through a median laparotomy at Dover Castle Station Hospital on Sunday last for a very large diffuse aneurysm involving the common femoral and external iliac arteries. Reports made up to date state that the patient is doing well. The operation was performed by Brigade-Surgeon-Lieutenant-Colonel W. F. Stevenson, assisted by Surgeon-Major Whitehead and the officers of the hospital. We hope to give a full report of the case later.

The Secretary of State has sanctioned the amalgamation of the three branches (Bengal, Madras, and Bombay) of the Indian Medical Service into one service under the administrative control of the Government of India, and has also accepted a proposal that the Surgeon-General with the Government of India should be the head of the amalgamated service under the designation of Director-General of the Indian Medical Service.

A dinner was given on the 11th inst. by the officers of the Army Medical Staff at Shorncliffe to Brigade-Surgeon-Lieutenant-Colonel J. H. Reynolds, V.C., who will shortly retire from the service.

Correspondence.

"Audi alteram partem."

THE "PRIMARY" EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—In sequel to a letter *re* the "Elementary Examinations in Anatomy" in THE LANCET of Oct. 19th of this year, I propose to say a few words about the Second Examination or "Primary." This is an examination in which candidates are expected to have a fair knowledge of human anatomy and physiology. The candidate is not admitted to it unless he has previously passed an examination in elementary anatomy, biology, chemistry and practical chemistry, materia medica, and physics. I think I have shown pretty clearly that the examination in elementary anatomy is practically a useless one, or worse than that, one which instead of being a real help to the student is a drawback, and one which might readily be dispensed with as it is in the London University examination, because in the majority of cases it causes a student to waste much valuable time in his first winter and, worse than that, demoralises him. The Second Examination is really a good all-round one, so far as its requirements go, though its results are often startling and unaccountable; but that one can be prepared for to some extent in any examination which is conducted by an examining board when the members of which for the most part know nothing of the college work of the student. These results, as I have before said, are sometimes startling, many students sometimes passing who scarcely ought to pass, and many others failing who ought certainly to pass.

In an examination partly conducted by teachers such results could scarcely come about because one examiner at least knows what the candidate knows by what he has done in the class examinations he has from time to time as a teacher conducted; but in such an examination as that held by the Royal College of Surgeons, and especially in the *vivâ-voce*, which lasts only ten minutes, some grave errors are constantly committed. The element of luck largely enters into such examinations, and thus the most ignorant student may pass, and frequently does, whilst the hard-working, plodding, and conscientious student, who often is nervous because he thinks he may be questioned on knotty points which the more ignorant man never heard of, gets "ploughed." I am not speaking theoretically here—I speak from a large experience of both kinds of students. It may, of course, be urged that London University students suffer the same disadvantages, but that is not so: they have two papers on anatomy with usually not less than six or seven questions on them, and these are followed by a two hours' examination on practical anatomy, giving a student a much better chance of showing what he knows than when he has one "paper" of four or five questions followed by ten minutes' questioning. In the latter case a candidate is very much more the possible victim of circumstance. His examiner not knowing him may be curt, petulant, angry, sarcastic, tired, or indifferent, any of which conditions may upset the mental balance of the wretched candidate, especially if he be of the nervous type I have mentioned—and unfortunately the nervous men are, in the main, distinctly above the average, according to my experience, the most jaunty being usually the most ignorant—and he fails. He has worked well from beginning to end, and is naturally discouraged on knowing that his easy-going fellow student has passed. No one knows better than the teacher the injustice of the thing, and no one better than the provincial teacher. It seems to me that the provincial student labours under a greater disadvantage than the London student, for the latter has at least the satisfaction of knowing that there is a possibility of his teacher examining him, or at least being present during the examination (I do not by this cast the slightest insinuation of favouritism, but I mean that the student who is examined by his teacher must have a better chance of passing creditably than one who is not, because that teacher cannot but know something of the student's history).

It is unfortunate that so many of the examiners belong to London when so many of the candidates are drawn from the provincial schools. There are ten such schools in England alone, and I believe that there are only two examiners drawn from them. The regulations at present debar men who do not possess the qualifications of the Royal College of Surgeons of England, which means that the majority of provincial teachers are excluded, although they are for the most part entirely occupied with the teaching of anatomy. If these regulations are unbreakable, much still can be done. A certain amount of information as to a student's career could be obtained by so remodelling the "forms" for admission to the examination and adding to them a clause to the effect that the candidate's application must be backed up by a report of his work, along with the marks he has obtained in the "class examinations" held during the time prescribed for study. At present he is supposed to have attended "class examinations," but it seems to be a matter of indifference as to whether he obtained 1 or 100 per cent. in them. Obviously such a clause, as it at present exists, is useless.

Then there is another point which is of vast importance both to the teacher and the student. At present when a student passes the Primary Examination he passes, and there is an end of it. He may make 100 per cent. or he may make a modest 50; in either event he is neither better nor worse than his fellow, and he is none the wiser. There certainly ought to be some improvement here. I do not know what powers the Board possesses, but it seems to me that it would be a simple matter to add to a man's pass certificate, "with credit," or "with great credit," if the giving of "honours" be impossible. I think I am right in saying that this is now done in the triple qualification of Scotland. Could this be done it would alter the state of affairs completely. At present, as matters stand, the good student who has resolved on taking the "qualification" of the Conjoint Board has no inducement to do more than a certain amount of work, and the lazy student's mind is chiefly occupied with making the marks necessary to pull him through. It is very considerate of the College to regard

Digitized by Google

all the holders of its qualifications as being of equal intelligence; but it is an idea which is on the face of it untenable, and it has a bad effect on all concerned. Many a man would work with pleasure to pass his examinations "with credit" could he do so, and there is little doubt but that he would the more readily find employment after doing so, but as things are he knows that fifty marks are of as much value to him as a hundred, and he consequently directs his studies accordingly, not trying to get up as much knowledge as possible, but puzzling his brains chiefly with a view to finding out how much knowledge he will require to display in order to make the necessary fifty marks, and he is a clever teacher who can persuade a student to read in order to make fifty-one marks when fifty will suffice. We who have passed our examinations and are becoming fogeys, so to speak, find it easy to say that it is a student's fault if he does not make the most of his opportunities, but if we think for a moment of our student days I think we will admit that our enthusiasm for work was largely regulated by the opportunities we had of obtaining some definite recognition of that work. The seriousness of the question arises most impressively to the "newly qualified" man who seeks employment. Ninety-nine men out of a hundred have nothing by which they can claim greater recognition than their fellows. They can only say they have the necessary legal qualifications just as hundreds more have, and as to testimonials, the less said of them the better. It is a high ideal, no doubt, to suppose that every man possessing the M.R.C.S., L.R.C.P. is as good as his fellow M.R.C.S., L.R.C.P., but in these matter-of-fact days ideals are little more than ideals, especially where employment and the making of daily bread are concerned. If there be any objection at all in the giving of a student credit for the work he does, it is in giving it at the time when he does that work; in other words, when he passes his examination. To be more precise, it may be argued that it is a bad thing to indicate to a student that he has obtained credit in a certain subject at the time of passing that examination, because it may cause him to specialise in one subject to the neglect of the other. That is certainly a serious objection, but one that could easily be got over by announcing at the time of passing the Final Examination the subjects in which the student has distinguished himself. I am sure that this is a proceeding which would give the greatest satisfaction to all candidates for the M.R.C.S. and L.R.C.P. and to medical men requiring assistants; in fact, many members of both classes have assured me that they would hail with the greatest possible satisfaction such an innovation. I feel very strongly that the much-vexed questions of "a degree for London students" and "a Teaching University for London" are the outcome of an honest desire on the part of qualificates of the Royal Colleges of Surgeons and Physicians to show something more for their work than the mere letters M.R.C.S. and L.R.C.P.; and I feel sure that there would not be the unseemly squabbling over who is to be called "Dr." and who not if men could obtain a diploma of which they might be proud, one which would be a certificate either of ability or hard work, or of both.

I am, Sirs, yours faithfully,

EDWARD FAWCETT, M.B. Edin.,
Professor of Anatomy, University College, Bristol.

Nov. 5th, 1895.

"THE ADMISSION OF WOMEN TO THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—I have read with great interest the two letters that have appeared in THE LANCET of Nov. 16th in reference to the question of women being admitted to the examinations of the Royal Colleges. Having been present at the general meeting of Fellows and Members of the Royal College of Surgeons of England on the 7th inst., I heard the views expressed on both sides, and I think that Mr. Hastings Gilford's letter represents as a whole the general feeling of the Fellows, and that of Mr. A. S. Morton the consensus of opinion among the majority of the Members who were present. The latter's remarks are quite in keeping with those made by the Members who spoke on that occasion, and it seems to me not a little surprising that the antagonists of the ladies are not able to advance any more sound or cogent reasons for their opposition than have hitherto been expressed. One Member remarked that it was a horrible sight to see women operate, to which he received the immediate answer that it was also a horrible sight to see some men operate. Again, he said that women were incapable of arresting hæmorrhage by reason of their tendency to faint at the sight of blood, and ingeniously added that *he* had never seen a man so affected. To this I may say that those who have had long experience at our medical schools know that men often faint at the sight of blood, whereas nurses rarely if ever do.

Such statements as the above quoted are evidently made at random, and Mr. Morton also falls into the error of thinking that mere assertion is argument. For instance, he says that ladies are "neither required nor wanted" (*sic*) on the roll of the Royal Colleges, but surely this is no reason for their non-admittance; for are there not many men yearly obtaining diplomas from the said Colleges who in the present overcrowded state of the profession may equally be considered as "neither required nor wanted"? Nevertheless, on this plea we do not bar their way. In another part of his letter he asks, apparently with fear and trembling, "What is to prevent women, in the event of their taking the Fellowship of either College, from occupying the professorial chairs?" adding that in that case we should have the "glaring anomaly of women teaching the men," and pathetically exclaiming, "This is no fancy picture." On this point, I fear, there is little consolation to offer him, for if women ever attain a greater amount of knowledge than men it would surely be more glaringly anomalous were the latter to refuse to profit by their teaching on the trivial question of sex. Again, he asserts that "from a recent glaring case women, from their teaching and practices, are prepared to inculcate acts of direct and open immorality." Must we infer from this that Mr. Morton is not more logical than to generalise from an individual instance?

If no sounder reasons than the above can be advanced against the women's claim methinks it were more comely to preserve silence on the subject, since the only construction that can be put upon these views is that they arise from mere dread of competition. Indeed, that this fear is the main reason for the hostile attitude displayed by the opposition party I have no doubt whatever.

It were regrettable if these gentlemen have come to such a pass that they should strive to do away with so great an incentive to progress. Is it not the very competition that we are open to that creates within us a spirit of emulation—that inspires us to achieve greater things! To fear competition, then, and to be jealous of a neighbour's chance of success, is verily an acknowledgment of weakness. On the other hand, to defy competition by manfully keeping abreast of the times by an ever-constant pursuit of knowledge is surely a more worthy course to follow for the purpose of safeguarding and preserving professional status than to resort to the baser means of barring the doors to new-comers.

In conclusion, I would say that if the body of Members wishes to have a voice in the management of the Royal College of Surgeons of England, it must see that its representatives are able to decide questions of importance without prejudice or jealousy, and so show themselves possessed of that width of learning and depth of general culture so essential to those who hold the reins of government.

I am, Sirs, yours faithfully,

W. ERNEST MILES, F.R.C.S. Eng.

Kensington, W., Nov. 18th, 1895.

To the Editors of THE LANCET.

SIRS,—I rather fancy that Sir Walter Scott was to blame in having had his share in the production of the "new woman," for was it not he who sowed the medical seed in the female mind by commenting, in an unguarded moment, upon the value of woman in the sick room? It is natural to suppose, however, that the "ministering angel" of his imagination came armed only with the average feminine attributes, rather than brandishing a medical diploma in one hand and a catheter in the other. In any case, it certainly seems strange that the medical profession—and by this I mean the actual practice of the profession as distinguished from nursing—should attract women; but no doubt it is, as Mr. Gilford remarks in his letter, one of the signs of the times, for the new woman is, *par excellence*, a morbid product, and it is, therefore, quite intelligible that she should wish to study morbid anatomy.

Digitized by Google

We shall one day have a reaction and find women anxious to resume their time-honoured *rôle* of "guardian angel," and then, perhaps, they will invade the pulpit, where, after all, they will be less out of place than in the Presidential Chair of the Royal College of Surgeons of England. They are far more suited in every way to be our moral and spiritual than our physical advisers. Mr. Morton has grasped all the salient points of the question, and in his letter has ably set them forth. He has shown that female physicians are now no longer a necessity in India, and he has politely implied that they are a luxury that England can dispense with. He has pointed out the absurd possibility of women occupying professorial chairs. In this connexion one cannot help calling to mind that graceful and fantastic and withal prophetic satire, "The Princess," which Mr. Gilford would not consider up to date, seeing that the Laureate depicted his ideal woman as being "not learned save in gracious household ways," and as one who cares not "to walk with Death and Morning on the silver horns."

In conclusion, I think the profession owes a debt of gratitude to the London Colleges for their joint verdict, and I regret that my own colleges should have succumbed to a spirit of gallantry.—I remain, Sirs, faithfully yours,

Reading, Nov. 19th, 1895. CLAUDE A. P. TRUMAN.

To the Editors of THE LANCET.

SIRS,—Having taken a personal part in the controversy at the annual meeting of Fellows and Members of the Royal College of Surgeons, *re* the admission of women to the Membership of the College, I beg to avail myself of your valued columns to emphatically refute a floating assertion that the majority of general practitioners view with favour the proposed admission of women, not only to the functions of the general practitioner, but also to those of the consulting surgeon and operator. Ask the majority of British husbands and fathers, comprising as it does the majority of general practitioners, whether they would desire to behold their wives or daughters performing surgical operations. Do we not daily encounter men, clear-headed in danger, generously ready to risk their lives for a good cause or to save that of a fellow creature, yet who sicken at the thought of even witnessing, still more performing, an excruciating surgical operation? We do not blame their humane lack of firmness. Do we, then, wish to see the gentler sex surpass even many a gallant soldier in sensibility? Divine wisdom has obviously assigned certain walks of life to the sterner, others to the fairer, moiety of our race; and when at the above meeting I seconded Mr. Joseph Smith's resolution I maintained, and do so still, that a woman who undertakes the revolting though beneficent duties of the operating surgeon unsexes herself thereby. In this country at least—nay, in all the long-established nations of Europe enriched with a practical experience of ages still lacking to newly constituted communities of colonial origin—we see the law still keeping its portals closed to aspirant female practitioners, the Church still more peremptorily denying the gentler exercise of its ministry to women, because the consensus of ages is that, however admirable her mental endowments in many respects, even the Christian pastorate, still more so the acrimony of forensic debate (itself repulsive in many criminal cases to her innate modesty), do not offer her own special good qualities a suitable field of labour. Her sphere is home—it is nothing, a mere empty sound, without her to adorn it. The more genuine she is, the more man looks up to her; and, when compelled to earn an intellectual living, at least let her eschew duties from which a courageous and strong man may be excused for recoiling. I am, Sirs, yours faithfully,

J. BRINDLEY JAMES,
Surgeon, Municipal Throat and Ear Infirmary.
Bridge-road, Hammersmith, W., Nov. 18th, 1895.

To the Editors of THE LANCET.

SIRS,—More than a century ago the spurious doctrine of "Égalité" promulgated by Hobbes and Rousseau was, to a certain extent, a factor in hastening on the Revolution of 1789. Men are not equal intellectually, physically, morally; and so far as the individual possesses these attributes singly or collectively in excess of his fellow men, so far will the gulf which divides them widen. Now, Sirs, as concerning medicine, a worse doctrine than the above presents: as men are unequal, how much more is this inequality shown by the admission of women into the profession, and by the fact of such admission placing them upon the same footing as men and acknowledging them as equally fitted to perform the duties of practitioners. From all points of view, as has been already expounded in your journal, they are from their constitution unfitted to practise medicine, and their admission into the profession will only tend to cheapen and degrade what is already an overcrowded calling. There are many men who would be only too glad to give up practising in open surgeries and dispensaries in exchange for higher fees &c. were it not that they are compelled to live by their profession. The Royal Colleges in London have acted wisely in refusing, by their late decision, the admission of women to their examinations, and it is the duty of those who are responsible to keep up the traditions which have been handed down. I remain, Sirs, yours faithfully,

Nov. 18th, 1895. M.R.C.S.

"THE PHYSIOLOGY OF DEATH BY ELECTRIC SHOCK."

To the Editors of THE LANCET.

SIRS,— I have much pleasure in replying to Mr. Fotheringham's courteous letter in THE LANCET of Oct. 12th. The point about which he desires some further explanation is the nature of the influence exercised upon the natural functions of the body by the opposition of similar magnetic poles. Mr. Fotheringham says: "Granting for a moment that no more complex result might be expected from the opposition of similar magnetic poles, is it reasonable to suppose that such a radical change of direction as the one under consideration could take place without causing some very distinct modification of the natural functions of the body? The fact that no such modification actually occurs when the living body is introduced into the most powerful magnetic field—no matter in what position the one may be placed in relation to the other—would appear, I think, to tell very strongly against the validity of Dr. Shettle's theory." In discussing this question I would first call attention to the fact that all the constituent elements of the body are polar—i.e., they manifest magnetic or diamagnetic properties; and, secondly, I would point out that chemical action, by which the various processes of life are naturally maintained, is identical with electric action and is essentially a polar force. The question to be considered, therefore, is why, and to what extent, are these polar forces capable of being modified by external force of the same description without changing the character of the phenomena? A brief reference to some experiments which I made upon bar magnets some years since may throw light upon what takes place in magnetic atoms when subjected to force from various directions.

Taking two bars of steel, as equal in magnetic power as I could render them, I placed them together in every sort of position, and by watching the behaviour of fragments broken from the pointed ends of needles I examined and tested the lines of magnetic force in every instance. To make a long story short, one result of these experiments was to prove that the cause of the poles of a bar magnet not being situated respectively at its extreme ends, but at some little distance short of them (as determined by the late Astronomer Royal), is due to the effect of lines of reactionary force which pass from the ends of the bar to meet those which come from the equator, the polar line marking the position where these forces collide and are ejected from the bar. It is absolutely necessary that I should explain how I arrived at this conclusion, because it has a very important bearing upon the cause of magnetism. When two similar poles of bar magnets of equal power were approximated the needle points, which had been placed on the line of the magnetic pole of each bar, fell, and they could not be made to resume their more or less vertical direction until they were placed over the line of contact of the two bars; if the magnets were of unequal power the polar line would be found on the stronger bar, and in proportion to the disparity of force between the two magnets it would be at a greater or lesser distance from the bar end. The other positions assumed by the needle points as they approached the new polar line from either direction were identical with those which they took on a single bar magnet when moved in the direction of the polar line. On the other hand, when two dissimilar poles were placed together almost all polar manifestations

Digitized by Google

vanished, and the phenomena at the point of contact then tended to become like those at the equator of a single bar magnet; and they might be compared to the magnetic phenomena which are exhibited by a copper wire whilst conducting an electric current. By these and other experiments I have satisfied myself that one of the distinguishing differences which exist between magnetic and diamagnetic matter resides in the property which magnetic matter possesses, by the induction of reactionary force from the bar ends, of throwing outwards from its poles the force which has traversed it from the equator to the poles, which property diamagnetic matter does not possess, although a diamagnetic copper wire, as I have stated above, *whilst transmitting a current* is magnetic transversely to its axis.

In my letter of Sept. 28th I drew attention to the supposition that the molecules of soft iron are magnetic, but that they do not manifest polar phenomena because they have no definite arrangement, the polarity of one molecule neutralising that of another. Now this has a very important connexion with the condition of the columns of blood as they traverse the body. That this is so is readily recognised when we consider that the blood is composed of corpuscles and liquor sanguinis. The corpuscles in both the venous and arterial states are magnetic (as proved by Dr. A. Gamgee), but they float in a highly diamagnetic medium, and, as I have shown, they are more highly magnetic in the arterial state in proportion to the oxyhæmoglobin which they contain. Consequently, the blood columns may be compared to soft iron, with this difference—in soft iron the molecules have great capacity for magnetism and are closely packed together, whilst in the blood they are at most but feebly magnetic and are also comparatively widely separated. They are, moreover, during life undergoing *very rapid motion*, and therefore are but little liable to retardation from any influence which might be exercised upon them by the strongest magnetic poles. Again, if the blood is in the same state as soft iron there would be no definite arrangement of the molecules so long as they remain in the larger vessels. But when they are passing through the capillaries each corpuscle is most intimately associated with the terminal nerve fibres, and still more closely with the lines of terrestrial magnetic force, and the magnetic energy of the moving body in proportion to its intensity would promote action and reaction with these lines of terrestrial magnetism. Unless, therefore, we set aside one of the fundamental principles of magneto-electricity, it is obvious that these corpuscles are bound to originate currents of energy in the nerves in proportion to their magnetic force; and this notwithstanding the fact that the general direction of the polarity of the molecules aggregated into a mass may be modified by external force. I thus show that the magnetic force—i.e., the specific energy—of the blood corpuscles is manifested in the power which resides in them of inducing current energy in the nerves, or of doing work upon them, through the influence of the terrestrial magnetic force, when they are most widely separated from each other but most intimately associated with the nerves in the capillaries, and therefore at a time when they would be as little as possible subject to the influence of external force of the like nature.

I have now to consider the relations which exist between the molecules of matter in the liquor sanguinis, which are not of the nature of blood corpuscles, and an external magnetic force. Unquestionably the polarity—i.e., the specific energy—of each of these molecules must be elicited to the largest extent under this inductive influence; but here again I think there is abundant evidence that no such change in the condition of the molecules as Mr. Fotheringham supposes would occur, but rather that the natural powers of tissue formation would be increased. Thus:—1. Every molecule, in proportion to its specific energy, would tend to modify the direction of the artificial force. 2. The extent of this modification would depend (*a*) upon the number of molecules engaged in its production, (*b*) upon their state of aggregation, and (*c*) upon the state of rest or motion in which they existed. Now the parts of a body which would be principally affected by any artificial polar influences to which it was subjected would be primarily the formed structures, which are stationary and in which the molecules have been converted into solids of greater or less density, instead of fluids in which the minute molecules are freely suspended and float about more or less widely separated. Again, each of these tissues would continue to exercise the specific energy of its constituent molecules in definite lines, only with greater intensity in proportion as they are more closely packed and are subjected under such conditions to the polarising influence of the magnetic field in question. The molecules in the nutrient fluid would be similarly affected, and greater energy—or power to point in a definite direction—would be imparted to them, both by the influence of the artificial magnetic field and by the energy of the formed tissues. Thus each molecule would acquire its precise character and would be deposited in its normal situation whilst it was subjected to an abnormal amount of polarising force from these two sources, both of which must, more or less perfectly, coincide, and in proportion to any excess of artificial energy derived from an external source the tissue formation would be more compact and its energy greater. Therefore in all respects the abnormal force would be productive of beneficial rather than of injurious results. In substantiation of these views being correct I will refer to the process of crystallisation. In this process the molecules of several forms of matter may be held in one solution, and yet each form of matter will be attracted and deposited upon exactly that part of its primary crystal as will ensure oneness of matter and of form in each. Now it is very difficult to perceive how the original crystals exercise their natural powers in this manner until we recognise that each molecule exercises its specific energy through its specific polarity; and, further, that the whole of the elements engaged in the work are immersed in a magnetic medium. Then the whole process becomes clear enough, for as soon as some slight molecular motion has been set up and the magnetic field has been thereby disturbed the specific polarity emanating from the already formed crystals is exercised upon the adjacent molecules, and through them upon the molecules at a distance, with the effect of attracting and depositing some molecules upon their surfaces and of repelling others; thus the exact form of the original crystal is maintained. Now, the fact is well known that apparent rest of the mother liquor is essential to the formation of perfect crystals, and that matter of any kind when thrown into rotation tends to take the spheroidal instead of the angular form. The cause of this modification is, of course, due to the rotation, and I think that the conclusion is equally logical that the cells of the living body take the spheroidal form owing to the motion to which they are persistently subjected whilst they are being converted into the various tissues under the attractive and polarising influences emanating from the formed and forming tissues.

I think I have thus shown good and sufficient grounds for the view which I hold that neither the magnetic nor the diamagnetic forms of matter which compose the living body could be injuriously affected by subjecting it to the influence of the strongest magnetic field. I wish further to state that I had two objects in view when I added my quota to the correspondence in THE LANCET upon the Physiology of Death by Electric Shock. One was to explain the cause of the arterial system being comparatively emptied and the venous system gorged with blood; the other was to show that the force which, by its intensity, causes death is identical with that which, when its action is regulated by the motion of the particular forms of matter engaged in building up the material body, maintains the phenomena of life.

I am, Sirs, yours faithfully,

Reading, Oct. 19th, 1895. RICHARD C. SHETTLE.

P.S.—Since writing the above I have read in THE LANCET of Oct. 26th Sir George Johnson's letter. From the manner in which Sir George Johnson refers to my statement "that the absence of oxyhæmoglobin in the blood after death by electric shock is a fact beyond dispute," it would appear that he understood my words to imply that such a condition of the blood is only produced by electric shock. I did not intend to convey this idea, for this state of the blood is also produced by the prevention in any way of the due aeration of the blood, and, moreover, it is the natural result of the blood's normal circulation through the system. I regret that any want of clearness in expression on my part should have given rise to this misconception. My views as to the effect of the electric shock upon the oxyhæmoglobin may be best explained by reference to a very simple experiment—viz., the synthetic production of water by passing an electric spark through a mixture of the gases oxygen and hydrogen. When this is done the oxygen and hydrogen are combined and condensed into the highly diamagnetic liquid water, the magnetic character of the oxygen being temporarily suppressed. In my opinion, a physical change which is in character almost identically the same occurs in the

blood under the influence of electric shock; for oxygen is instantaneously combined with a carbon and diamagnetic substance is formed, and the oxyhæmoglobin simultaneously disappears. With regard to the interest which centres in "What is Life?" I would remark that the cause and nature of animal life are as essential to scientific medicine as a knowledge is to the engineer, for the proper construction of his mechanisms, of the natural forces by which those mechanisms will perform their work. In a very few words I will endeavour to render my meaning perfectly clear. It is well known that in steam and electricity we have two great forces, and by a careful consideration of their nature forms of mechanism have been invented capable under their power of doing almost any kind of work. In the foregoing letter I have endeavoured to show the manner in which the arterial blood does work upon the force of terrestrial magnetism, and terrestrial magnetism upon it, and how in this way that great natural force is utilised so as to cause the evolution of those phenomena which are natural to the living body. But the mechanism of the living body is constantly being impaired by the introduction of material impurity, and therefore it is that a full knowledge of the mode in which matter is productive of its effects, and also a knowledge no less full of the essential nature and conditions of that life the establishment of which in its truest environment and most perfect state is desired, become of such vast interest to the physician as well as to the human race in general.

"THE BATTLE OF THE CLUBS."

To the Editors of THE LANCET.

SIRS,—Our "Battle of the Clubs" here has reached this stage—that there are four outside competitors against the present holder—no local man is contesting. There have been other candidates, but they have been induced to withdraw. The present holder refuses to take infants and girl juveniles under 4*s*. per annum. May we ask your assistance in appealing in the columns of THE LANCET to these men, urging them to withdraw? I may, perhaps, add that the outside men have tendered for the infants and other juveniles at 2*s*. 6*d*., 2*s*., and 1*s*. 6*d*. per annum. There is absolutely nothing personal against the present holder. This battle was brought on by the Loyal Benevolent Lodge requiring him to attend infants from three months and juveniles of both sexes to fifteen years for 2*s*. 6*d*. per annum. The local profession is united to a man. If we can only win this fight there are many other reforms open to us with every chance of success. I am, Sirs, yours truly,

FREDERICK PEARSE, Hon. Sec.

Portsmouth Medical Union, Pembroke-road,
Portsmouth, Nov. 17th, 1895.

To the Editors of THE LANCET.

SIRS,—Your Special Commissioner has hit upon one of the chief difficulties in dealing with the club question at Hull. When the medical aid system was first imported into —— it was almost unanimously condemned by the resident practitioners. Its first medical officer undertook his duties knowing that so far as —— was concerned he would have no support from his professional brethren. The result was that this gentleman obtained a free hand, without competition, amongst several thousand people, and could always obtain a consultant from other towns when the nature of his cases required a second opinion. Our united action was therefore inoperative, and gave the suspicion that we were actuated entirely by selfish and personal motives in our repudiation of an institution of a philanthropic character, supported by the tacit approval of the leading members of the profession in the district, and by many influential and respectable townsmen. Finding also that in a case of grave emergency it was difficult to adhere to our resolution we abandoned our position, not because we considered it unjustifiable, but because we were advertising an institution whose methods we disapproved. At present consultants are little touched by this contract question, though it will doubtless affect them in their turn if they countenance the present system of provident medical aid. The snake which they warm will sting them in the pocket. Sir Dyce Duckworth said plainly at Southampton what he thought of medical aid ethics, but the thing goes on in spite of his and other protests, and will go on until we learn that it is the common interest of the profession to protect itself from the imposition of a pauperised public. Many a consultant who would tremble to meet a homœopath does not hesitate to throw the mantle of his protection over the covering of a lay committee in practice for gain by a medical man, whom they make absolutely their servant, and whom they sweat or dismiss at their own sweet will. While this is the case combination to regulate club practice is impossible.

I am, Sirs, your obedient servant,

J. B. PIKE.

"INFANT CRIMINALS."

To the Editors of THE LANCET.

SIRS,—On your most valuable Annotation in THE LANCET of Oct. 26th last, on the above subject, I beg to offer a few remarks. The family medical practitioners' duties, of necessity more than any other class of the community, compel them to observe the daily domestic lives of mothers and children. The accurate information, stated in your remarks to be so much needed, can only be obtained from the general practitioner who has almost daily opportunities of observing from birth the different phases of existence. Looking at this vital question from a domestic and clinical aspect, I am of opinion that we are too conventional in our ideas of heredity, skull and face formations, and I fear these stand in the way of realising the full importance of infant mental management. We who have lived long enough have over and over again seen the cruel, lying, selfish, and vicious child of the fat, dirty, lazy, and fatuous mother sent to the infant school, where the ethical law has been habitually and objectively hammered in, and, despite the surroundings, not only has the child passed on into becoming a good mother of a family, but also by precept and example taught her children in the way they should go. What are much needed, as I have advocated in your columns and in other journals, are fixed laws for the homes, bearing the stamp of coöperation and authority. We who have so long moved among the masses feel what influence an applied system would have, and how willingly many would carry out rules of guidance while dealing with infant development and abnormalities. Further, while acting on "the hygienic imagination" with a "time-table" hung up in the homes, we know how much in the decent ordering of life dormant ethical law can be aroused and appreciated.

I am, Sirs, yours faithfully,

Londonderry, Nov. 2nd, 1895. WALTER BERNARD.

*** Dr. Bernard forwards to us with his letter a "time-table" to be hung up in cottage homes as a regulation of domestic affairs. There is no doubt that the orderly and accurate observance of the simple rules of health and cleanliness that he enjoins in the document would conduce to a sanitary and also a happy home.—ED. L.

"THE PICRIC ACID TEST FOR SUGAR IN THE URINE."

To the Editors of THE LANCET.

SIRS,—Pressure of work in connexion with the opening of my session and otherwise has hitherto prevented a reply to the recent letter of Sir George Johnson. I stated that if a solution of caustic potash and about an equal quantity of a saturated solution of picric acid be added to perfectly normal urine, a reddish colour is produced in the cold, and that when this solution is boiled the fluid assumes a deep claret colour. The same result ensues if the picric acid solution and the caustic potash solution be added to saccharine urine in the cold. On boiling, a deeper colour results in the latter case, the intensity of the colour depending entirely on the amount of glucose present. If the amount of glucose be small the colouring is not deeper at first than that which results in the case of perfectly normal urine. In this sense the picric acid test is, in my opinion, fallacious. Further, the solution gradually becomes of a darker colour on exposure. That Sir George Johnson himself maintains that the intensity of the carmine colouring is due to the proportion of sugar is evident from his recommendation of the picric solution as a quantitative test, the proportion of glucose being determined by the varying shades of colour. Sir George Johnson states that "the reddish colouration with picric acid and potash at the ordinary temperature in urine, whether normal or saccharine, is due entirely to

Digitized by Google

kreatinin, the strongest solution of glucose having when cold no reducing action on picric acid and potash until after an interval of at least an hour." I agree that glucose alone has no reducing action on picric acid solution and caustic potash in the cold, hence I agree with Sir George Johnson that when a certain reducing action takes place in the cold, as above, the reducing agent is some other than glucose; but whatever this reducing agent be it causes as deep a colouring on boiling as the glucose does in small quantity. I further stated that if the urine be rich in uric acid the colour produced on boiling with picric acid solution and caustic potash is deeper than in the case of ordinary urine, and to this Sir George Johnson assents, only Sir George Johnson contends that the greater intensity of the colouring is due to kreatinin. All I would say on this point is that my investigations have not satisfied me that kreatinin has anything whatever to do with the colouration in question, the colouring produced, as above, on boiling being as deep without as with it. Under these circumstances I consider myself entitled to maintain that the picric acid test for sugar in the urine is an "eminently fallacious" one.—I am, Sirs, yours faithfully,

D. CAMPBELL BLACK, M.D.,
Professor of Physiology in Anderson's College Medical School.
Nov. 2nd, 1895.

"THE THERAPEUTIC VALUE OF INTESTINAL ASEPSIS."

To the Editors of THE LANCET.

SIRS,—As the therapeutic value of intestinal asepsis has formed the subject of some recent communications to THE LANCET, would you permit me to draw the attention of your readers to a method I suggested some time since[1] of administering, as an intestinal antiseptic, sulphurous acid in combination with other antiseptics and disinfectants? Dr. Emerson Reynolds, F.R.S., Professor of Chemistry in the University of Dublin, announced to the Royal Dublin Society in 1889 that if sulphur dioxide gas is brought into contact with camphor, the latter can liquefy the gas without any pressure whatever. The sulphur dioxide gas, he ascertained, could be kept in this liquid form in an ordinary well-corked bottle, at mean temperature, without sensible change; but was evolved freely and in relatively enormous volume from it when the liquid was exposed to the air. Recognising the importance of such a solution as a disinfecting agent, he further increased its efficiency as such by the addition to it of other volatile bactericides, such as benzoic acid, phellandrene (a terpene contained in Australian eucalyptus oil), &c. The resulting combination is patented under the name of Thiocamf. It is a unique, non-poisonous liquid, and although at present rather an expensive preparation for general use as a disinfectant, it has been largely employed as such, particularly, I believe, in the Library of the House of Commons during the influenza epidemic of 1891. For the last two and a half years I have given Thiocamf in a number of cases in which a gastric or an intestinal disinfectant was indicated, and with satisfactory results. It has been well tolerated, which cannot, as Dr. Leonard Williams remarks,[2] be always said of some of the most frequently used intestinal antiseptics. In the treatment of enteric fever Thiocamf, in my experience, is of much value. It appears to clear the tongue, relieve the intestinal distension, diminish the fetor of the fæces, and altogether to influence favourably the general course of the fever. I now prescribe it in gelatine capsules, each of which contains either one minim or two minims of Thiocamf, mixed with about eight minims of olive oil. The capsules may or may not, as required, be coated with keratine. I usually order one capsule three or four times a day. In some gastric cases in which an immediate action on the stomach or its contents is indicated the keratine coating may be dispensed with. Thiocamf is non-toxic. It is, I believe, a powerful germicide; and to this property, as well as to the probability, when given in keratine-coated capsules, of its reaching the intestine in a state in which its *volatility* may have some direct action, I would attribute the good effects of the drug. In addition to the advantages of Thiocamf as an intestinal antiseptic I may state that, as far as I know, the experience of those who have made a trial of it, internally and externally, in such cases as I suggested its employment in my preliminary note on its use, has on the whole been favourable. Satisfactory results have especially been noted when Thiocamf was given as a gastric antiseptic and antifermentative agent, and also when employed locally (in a 4 to 6 per cent. solution in olive oil) as a dressing for ulcers, &c., and as an antiparasitic application in the treatment of diseases of the skin, such as scabies and the tineæ.

I am, Sirs, yours faithfully,

GEORGE F. DUFFEY, M.D. Dubl.,
Physician to the City of Dublin Hospital; Professor of Materia Medica, Royal College of Surgeons in Ireland.
Dublin, Nov. 18th, 1895.

*** Dr. Duffey's letter raises an intricate question in regard to "patent medicines" and medicaments which are "patented." On general grounds it is manifestly inexpedient that the preparation of drugs for internal use should not be open to all chemists.—ED. L.

[1] Dublin Journal of Medical Science, May, 1893.
[2] THE LANCET, Oct. 26th, 1895.

THE LONDON SCHOOL BOARD AND MEDICAL CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—Since the School Board's resolution of May 30th, 1895, to appoint medical men "to examine cases in which the medical certificate produced is considered by the divisional superintendent to be doubtful" was passed, letters from no less than six London hospitals, including four hospitals for children, have, I believe, been sent to inform the board that medical certificates will in future be refused by the staff of such hospitals should the board's resolution be carried into effect. These letters from a large number of experts on the diseases of children, protesting against having the value of their certificates questioned by an ignorant school board superintendent, and possibly upset by medical men who for half-a-crown may be willing to undertake the duty, have been contemptuously ignored by Mr. Sharp of the School Board Attendance Committee.

Putting aside the question of medical etiquette involved (with which, by the way, Mr. Sharp has said the School Board has nothing to do), we may ask whether he and his colleagues are justified in treating the London hospitals with gross ingratitude. For many years the staff of hospitals, and of children's hospitals in particular, have rendered gratuitous and willing services to the School Board, both by keeping away children who might carry various forms of infectious diseases to school, and also by sending children there who but for them would be kept away by their parents. It is admittedly the case that parents will often keep children from school on a false plea of illness, and then when pressed by the board will bring them to the hospitals in hope of getting certificates of unfitness for school. Numbers of certificates for such children are daily refused by hospital physicians and thus the children get sent to school. These services to the board now turn out to be as thankless as they have been gratuitous. As regards children who are kept from school by medical men's orders, Mr. Sharp does not choose to know that a child may be well enough to run the streets and even to pick up a few pence for his poverty-stricken parents, and yet not be well enough to attend school.[1]

A child, according to Mr. Sharp, is a thing which must go to school unless it is ill enough to be kept in bed. The subjects of phlyctenulæ or of eye-strain and frequent torturing headaches; those with weak chests or irritable bladders; incipient choreics who, if neglected, may ruin their hearts and lives—are not within the ken of Mr. Sharp. If not in bed they must go to school, where they may be caned for having chorea, and if incontinent are not allowed to leave in order to obey the calls of nature. Cases of suspected epilepsy must be sent to school at the risk of becoming confirmed epileptics or imbeciles. Even imbeciles are not exempt, for quite recently attempts have been made to force to school a boy aged eleven who does not know that two halfpennies are worth a penny. The early symptoms of over-pressure—sleep disturbed by arithmetical nightmares; babbling of dates and capitals, and screams of fright; the causeless fits of passion or floods of tears; unwonted timidity and general nervousness—which are danger

[1] Report of Attendance Committee, Nov. 8th, 1895.

Digitized by Google

signals to medical men, have no significance for Mr. Sharp. If the children are able to be in the streets they are able to be at school. Children whose intellects are naturally stunted through ancestral causes must still go to school and be dragged from standard to standard, for Mr. Sharp's educational wine must be poured into brain bottles hereditarily cracked without reference to the result. Worse still are the cases of precocious intellects, which may be wrecked by allowing their possessors to learn too fast. Rich people's children can be protected from this evil, but the children of the poor are denied a similar privilege. They are children, therefore they must go to school.

What is the reason of this zeal on the part of the board? We learn from Mr. Sharp himself that it is purely a question of £ *s. d.* In his report of Nov. 8th he points out that an increase of 1 per cent. in the average of attendances per year means an increase of nearly £4000 in the Imperial grants. Hence it is that the maimed, the halt, the imbecile, and the blind must be forced to school in order to provide the board with money to fritter away on fads and fancies or on the decoration of their stately palace on the Embankment with, for instance, stained-glass portraits of the members. All children are baits for Government grants, and lest the supply should fall short, medical certificates given by competent men are to be rendered valueless at the dictate of school board inspectors. It is not likely that men who may be willing for half-a-crown to become the board's medical servants will run counter to their masters' views and protect children whom they are called upon to condemn. Surely it is time that the voice of the profession generally should be raised against the intolerable persecution of defenceless children and parents by the board in the name of education. The School Board bids fair to become a very Juggernaut.

I am, Sirs, yours faithfully,

Nov. 18th, 1895. HOSPITAL PHYSICIAN.

MEASLES AND THE CLOSING OF SCHOOLS.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me whether I, as medical officer of health, have the power of closing parish schools for an epidemic of measles, or must it simply be a recommendation on my part?

I am, Sirs, yours faithfully,

A CONSTANT READER,

Nov. 20th, 1895. Medical Officer of Health.

*** The law, as prescribed in the Code of the Education Department as regards all schools receiving an annual Parliamentary grant, is as follows:—"The managers must at once comply with any notice of the sanitary authority of the district in which the school is situated, or any two members thereof, acting *on the advice of the medical officer of health*, requiring them for a specified time, and with a view to preventing the spread of disease, or any danger to health likely to arise from the condition of the school, either to close the school or to exclude any scholars from attendance, but after complying they may appeal to the department if they consider the notice to be unreasonable."—ED. L.

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1257.)

MEDICAL ETHICS AND THE DISPENSARIES AT HULL.

THE friendly societies' dispensary at Hull was founded by eight lodges of the Hull and District Manchester Unity of Oddfellows. These eight lodges put down £1000 for that purpose. There were, however, four other lodges of the same society belonging to the Hull district who refused to take part in the forming of a dispensary. The reason they gave is all-important. They argued that it was against the rules of the Oddfellows' Society to employ the funds of the society for trading purposes. Thus four out of the twelve lodges that compose the Hull district of the Manchester Unity recognised that the opening of a dispensary was a trading enterprise. It is, therefore, at least an open question whether these friendly society dispensaries are not a distinct infringement of the rules of the societies by which they are established. Certainly, if a profit is made out of the services of the medical officers and the sale of the drugs, such dispensaries may well be considered as trading establishments. Perhaps the eight lodges of Hull would have hesitated to embark on such a venture had they foreseen that the four other lodges would not support them. But I was given to understand that financial responsibilities had already been incurred, and the large house in Saville-street, where the dispensary is established, had already been taken. All this occurred some twenty years ago, and several medical men with whom I discussed this matter admitted that some club officers had, by their neglect of club patients, brought upon themselves the creation of the friendly societies' dispensary. One of the leading physicians in Hull eloquently pleaded that the neglect of club patients was very wrong in itself, and that it was also a most short-sighted policy. Certainly it was very difficult to give proper attendance to patients who only paid 2*s.* 6*d.* a year. There would always be a tendency to neglect such patients, particularly if at the same moment there was a call from a private patient who paid proper fees. But, on the other hand, it was quite reasonable to suppose that the club patient, finding himself more or less neglected, would be tempted to join the movement for the creation of dispensaries where the medical officers would be employed by the members of the clubs, paid a fixed salary, and debarred from engaging in private practice. It is of no use to disguise the fact, mentioned to me at Lincoln, and forcibly insisted upon at Hull and elsewhere, that the creation of dispensaries by the friendly societies was a counter move against the club medical officers, who did not treat their club patients with the care and consideration to which they thought themselves entitled. A club officer at Hull told me he knew of clubs that paid their medical men only 2*s.* per annum per member, and he had himself had many members who paid him not more than 2*s.* 6*d.* a year. But—and this struck me as being a very significant declaration—he added that he always sought to impress upon them that they ought to pay more. In the rough and familiar form of argument, which can best be understood by that class of people, he was in the habit of pointing out that they could buy calico for underwear at a little more than 2*d.* a yard; but they all knew it was cheaper in the long run to pay about 4*d.* a yard. Nevertheless, the argument seems to be better appreciated when dealing with calico than with medicine; for the medical man in question had only the other day lost a club appointment because he wanted 3*s.* instead of 2*s.* 6*d.* a year per member. For my part, I could not but think such argument very degrading. The medical profession ought to place itself far above all such commercialism, and the attendance given to a patient should depend wholly and solely on his physical condition and not on the amount he pays. If once medical men lower their profession to the commercial level, then there is no reason why they should not be subjected to the laws of supply and demand and become liable, like other workers, to be ground down to mere starvation wages. The example of the highly educated and refined lady governesses who have so overstocked the market that they cannot earn as good wages as ordinary, uneducated cooks and chambermaids stands before the medical profession. If practitioners are going to compete against each other as to who can run a club at the lowest rate, the rate will soon reach that of starvation wages. Indeed, when I find on calculation that club medical officers give consultations and pay visits at 2*d.* and 3*d.* each, starvation does not seem far off. From all this it is only natural to conclude that great harm has been done by treating club patients hastily and neglectfully because they were only club patients and paid very little. Every conversation I have had on the subject has helped to show that, under all circumstances, the patient must be treated with every possible care and kindness. This is necessary, first and foremost, for the sake of humanity and the honour of the profession, and, secondly, because it is by far the wisest policy. Starting from this basis, club members must be made to pay much higher subscriptions if such practice is accepted as a means of livelihood; but it may be justifiable to accept club practice at a much lower rate of subscription if it be clearly understood that the work is to be undertaken as one of charity. In these cases it is absolutely indispensable to establish a wage limit.

Digitized by Google

On the other hand, by taking club patients on the principle of giving them only scant attendance in exchange for scant pay, the medical officer discredits himself and his profession and helps to justify the formation of dispensaries by the friendly societies.

The Hull dispensary started by the six lodges of the Oddfellows' Society was very fortunate in the selection of its first medical officer. This gentleman gave great satisfaction to the patients, and consequently the number of members increased rapidly. But still the six lodges were not enough, so it was decided to take in other societies. Any friendly, trade, or other society within a three miles' radius was admitted on the payment to the funds of the dispensary of a sum of not less than 3*s.* per member per annum. Individual members were also admitted on payment of an entrance fee of 6*d.* and an annual subscription of 3*s.* 6*d.* The wives and families of this institution are admitted on the payment of 4*s.* 6*d.* for the wife and 5*s.* for the children, irrespectively of their number, if they are under eighteen years of age. No member, unless he be a widower, is allowed to subscribe for his children unless he also contributes for his wife. Widows whose children are entitled to medical aid at the time of the husband's death are charged only half the usual subscription, and if the mother also dies her orphan children are entitled to medical aid till they attain the age of eighteen years free of all cost. Juvenile branches, however, have been formed, consisting wholly of members under eighteen years of age, and they are only charged 1*s.* 6*d.* per annum per member. Such are the principal conditions of membership. As for the duties of the medical officer, he must have both medical and surgical qualifications and reside at the dispensary, where, however, he lives rent free. He is responsible for the state of the laboratory, surgery, and waiting-rooms, which are situated on the ground floor below his private dwelling; he must keep these places clean and in good order. Then he must submit to the secretary of the dispensary a list of all drugs and medicines required and check all bills. The rules further stipulate "that the medical officer or any other to be appointed shall not engage in private practice, professionally or otherwise, either with or without remuneration, shall devote the whole of his time to the sick members of this institution, and shall provide all necessary surgical instruments." The medical officer has not only to attend to the sick but he must examine all candidates desirous of becoming members of the institution.

Under the first medical officer the income of the dispensary rose to from £600 to £700. What became of this income? The annual income has fluctuated considerably according to the popularity of the medical officer, and I was informed that at one time it fell as low as £350. Doubtless a portion of the money balance has been spent on improvements of the property, and there are the expenses of delegates to congresses &c. But, on the other hand, the committee works gratuitously. The committee consists of one delegate for each hundred members of the different lodges. This makes a very numerous and unwieldy committee. Nevertheless, this committee has been wise enough to augment the salary of the medical officer whenever the number of members subscribing has notably increased. Thus the medical officer participates in the prosperity of the institution. The interest of both the medical officer and of the institution is to increase the number of healthy members and to decrease the drug bill and the prevalence of sickness. No sort of attempt, however, has been made to establish a wage limit. Families in receipt of incomes amounting to several hundred pounds a year are treated at this dispensary for an annual subscription of a few shillings. In some cases expensive drugs have to be employed, such as morphia &c. Some rich members are treated for very trivial ailments, slight indigestion for instance, and want doses of pepsine, which very soon exceed in cost the 3*s.* a year they pay. Counting the cost of attendance actually given to a well-to-do family, members of the dispensary, it was shown that at 2*s.* 6*d.* a visit, medicine included, this would amount for the year to £25; yet this family only paid subscriptions to the amount of 9*s.* 6*d.*, and in this case expensive drugs were necessary. Many other such cases could be given. Indeed, Dr. Cameron, the secretary to the Hull Medical Society, told me he knew many smack-owners who belonged to medical aid clubs, and that, in his opinion, 20 per cent. of the members of such clubs could afford to pay fees. Nor was this a haphazard assertion. Dr. Cameron has been medical officer to many clubs, some of them numbering as many as 1200 members, so that his estimate is based on an extensive experience. It was but a few weeks ago that he refused the post of medical officer to a "female lodge" of a large Benefit Society on the ground that the "whole system tended to defraud the medical practitioner."

At the dispensary of the Hull friendly societies the medical officer enforces a rule which acts as a check upon the wealthier members of the society. He absolutely refuses to see anyone out of his turn. If someone is in a great hurry and asks to pass before his turn he is told it does not concern the medical officer; it is a matter which the patients must settle between themselves, and if anyone wishes to see the medical officer out of his turn he must obtain permission from the others who are waiting and not from him. This is a very good system, and, short of a positive wage limit, nothing would better help to keep rich men away from these dispensaries than their treatment on a strict equality with all the other members. But this is not always done. As already described, very special privileges are given at one town to wealthy members, though they do not pay a penny more than the poor. Then I have made another and very interesting discovery, though I must not betray my informant by stating in what town I was told of the fact. Suffice it to say that it was not at Hull. Originally club practice was a means of establishing a reputation and obtaining private practice. Then the friendly societies combined and opened in a great number of towns dispensaries where they employ medical men at fixed salaries, but on the condition that they shall devote all their time to the dispensary and have no private patients. Now, I have just discovered that private practice is like the traditional lover; you may throw him out of the door, but he will come in again by the window. One club officer, at least, has confessed to the soft impeachment, and I have not the slightest doubt that many others are guilty of the same little failing. Of course they have no private patients, but they privately receive extra fees. Not a few wealthier members of friendly societies desire better attendance, longer consultations, and more elaborate, expensive, and carefully prepared medicaments than can be given in the rough and quick practice of a dispensary. To secure these advantages from the club officer, game, Christmas turkeys, small cases of wine, or even direct fees in money are forthcoming; and thus the dispensary officer can create for himself a sort of private practice, which, however, must be conducted strictly "under the rose." This discovery appeared to me to be highly edifying. It seemed like the triumph of a natural law over the artificial law enacted by the friendly societies' dispensaries. These institutions tell their medical officer that, however much he may distinguish himself, however popular he may become, he shall still continue to give the best of his abilities for an average pay of 2*d.*, 3*d.*, or 4*d.*, as the case may be, per visit or consultation. It is true that the yearly salary may be raised if the society prospers, but this implies more members, more work, and therefore such increase only represents more pay because more work is done; it does not mean better pay. According to the sixteenth annual report of the Friendly Societies' Medical Alliance in 1894 there were 4000 members of the Hull dispensary, and 20,000 medical consultations were given and 7000 visits paid. For these 27,000 consultations the medical officers were paid £208. This sum is equal to 199,680 farthings, which, if divided by 27,000, shows the pay given for the medical service only amounted to a very small fraction above seven farthings per consultation! I am not responsible for these figures, I quote them; they are printed by the friendly societies themselves, and they are evidently too evenly rounded off in thousands to be absolutely accurate; but a farthing more or less added to the average remuneration earned by the medical man per consultation would not in any way affect the principle at issue. The fact remains that the pay is miserably, shamefully insufficient, and it is only natural that medical officers, by hook or by crook, should occasionally obtain more. That they sometimes succeed I have been assured by at least one among them.

Hull, Nov. 12th.

MEDICAL MAGISTRATE.—Dr. Arthur Flint of Westgate-on-Sea, J.P. for the Cinque Ports, has been placed on the Commission of the Peace for the county of Kent, on the nomination of Earl Stanhope, Lord Lieutenant.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Workhouse Dietaries.

THE Chorlton guardians have been experimenting for about seven months with a view to improve their diet tables. The old people often leave their food for want of a little change, and now it is to be varied by rice pudding and bread pudding. The young men have always had gruel, but are to have tea and bread-and-margarine occasionally, and the children are to have jam and fruit instead of margarine. The old dietary sanctioned by the Local Government Board cost 2*s.* 3*d.* per week for the old men, as against 2*s.* 3¾*d.* for the dietary now recommended. For the old women the cost will be increased from 2*s.* 1¾*d.* to 2*s.* 2¾*d.* For the young men the cost will be reduced from 2*s.* 4¾*d.* to 2*s.* 4¼*d.*, while for the young women it will be raised from 2*s.* 1¾*d.* to 2*s.* 2¼*d.* The chairman said the increase of cost was very little, while the variations in the dietary were considerable. One of the lady guardians said she "had heard the old people particularly say how pleased they were with their new dietary. The health of the inmates was considerably improved by a little variety."

Completion of the Gorton Sewage Scheme.

The purification of the sewage of the watershed of the Mersey and Irwell is slowly progressing. Gorton, with a population of 17,000 to 18,000, is a suburb continuous with Manchester, and until recently the drainage of the district went untreated into Gorton brook and Gore brook. But the Mersey and Irwell Joint Committee served the local board with notice to treat the sewage properly within a given time, and a scheme for so doing was prepared by Messrs. Lomax of Manchester. Land was bought near the Belle Vue Gardens, and the first sod was cut in 1893. The works comprise two detritus tanks with a total capacity of 110,000 gallons, and three precipitating tanks with a combined capacity of 1,079,000 gallons. The sewage on entering the works passes into the sludge or detritus tanks, having first received sufficient ferrozone to throw down the heavier suspended matter. It then flows into the three precipitating tanks, where the lighter suspended matter is deposited. Having thus been clarified, the sewage is conveyed by channels to six polarite filter beds having a superficial area of 2663 square yards, and the effluent at length finds its way into the brook. The works are designed to serve for an increasing population, and are capable of dealing not only with the sewage, but with a half-inch rainfall over the entire area built upon. At some future time it is intended to deal with the sludge deposited in the detritus tanks by means of filter presses, but that will be another undertaking. The present scheme has cost about £40,000. When the public opening took place on the 7th inst. the works had been in operation for three days, and the engineer said that on the previous night over a million gallons of sewage had been dealt with. "The effluent was remarkably clear, but they might yet have some impurities to contend with. If the polarite acted up to its reputation the organic matter would be reduced to a minimum." A gold key was presented to Dr. MacArthur, the chairman of the district council, from Mr. F. Candy, the managing director of the International Sewage and Water Purification Company, whose scheme has been adopted.

Baby Farming in Manchester.

An inquest was held on the 16th inst. on the body of an illegitimate child fifteen months old. The mother had placed the infant in the care of a woman in Hulme about twelve months before, paying 6*s.* a week and seeing the child once a month. This woman put the child into a burial club, but said she knew she would not be entitled to draw the money if the latter died while the mother was living. She had "minded" nine young children, of whom seven were illegitimate. Six out of the seven were insured by her, and three of them had died. She had had two to nurse at one time, and held no licence to nurse illegitimate children. Dr. Ashby, who made a necropsy, said the body was well nourished, but the bones were rickety, and the child died from asphyxia suddenly produced—as in spasm of the glottis. A neighbour gave the woman a good character, but no information was given as to the feeding and general management of the child, or as to the sanitary or insanitary condition of the surroundings. The coroner said it was dangerous practice to take in illegitimate children with proper authority, because if the medical man had not been satisfied that death had been due to natural causes the jury would have thought it, to say the least, a very suspicious case in view of the deaths of the other children she had had under her care. Whatever blame may attach itself to a girl with an illegitimate child to keep, her position is pitiable, for she can seldom earn her living while the infant is with her; if placed in the hands of one of these women the chances of the child living through infancy are small. Closer inspection and control are needed if the frightful mortality of these waifs is to be reduced.

National Association of Master Plumbers.

The first half-yearly meeting of the above association was held in Manchester the other week, and there was a large attendance of members. The President said that the former gatherings at Leeds and Sheffield had been concerned with the establishment of the association, but that the present meeting would be directed to an effort to remove the evils long known to exist in their craft. "Science represented by the medical world, had at last acknowledged that the plumber's work, thoroughly carried out under the guidance and direction of a competent plumber, was one of the most essential requirements for the sake of the public health." It is delightful to see "the craft" concerning which the medical world has often had something to say waking up apparently to a sense of responsibility for the public health. But if the public is to have good plumbing it must be prepared to pay more than the heavy charges often borne for bad work, for the address goes on to say "This recognition had brought forward so much more individual talent with special training and long study as entitled *bonâ-fide* master plumbers to be ranked among the professions, and entitled them to an equivalent for the increased confidence of the public and an increased remuneration for their work." This sentence seems a little mixed, but evidently the recognition of the fact that plumbing has an important bearing on health is to carry with it an elevation of the social status of the master plumbers, who are to rank with the lawyers, medical men, and divines, and to receive increased pay. In all events it will be satisfactory if from henceforth they prove themselves worthy of the increased confidence of the public. The chief paper read, with the discussion that followed, was intended to prove that corporations ought not to engage in plumbing work, and counsel's opinion was to be taken as to its legality. It appears that the membership of this new association is "spread over fifty-one cities and towns and sixteen branches." After this plumbing will surely cease to be a by-word and a reproach. In the poorer districts of Manchester the "pail system" is still in vogue, but some time since a resolution was passed in the city council in favour of making water carriage universal. The proposition, however, was not well received at a recent town meeting. The objections were various, cost being one. Much correspondence has appeared in the papers, and in addition to the cost, the great discomfort and inconvenience to all, the least, suffered by numbers during the long frost of last winter from the freezing-up of the waterclosets are brought forward as objections. Large numbers of the new closets are outside, and indeed the smaller houses are seldom adapted to their being placed inside, so that every winter the same trouble may be expected. It seems that the plumbers have not yet outlived their old reputation, for one writer dreads the consequences of the whole city being given over to "the plumber fiend." This is a strong term and no doubt undeserved. The plumber is powerful for good or evil, and it may be hoped that he will in the future always do good and conscientious work even when it is hidden.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Presence of Visitors in the Operating Theatre.

IN the Durham University Journal attention was recently called to the crowded condition of the area of the operating theatre at the Royal Infirmary, Newcastle-upon-Tyne. It was stated that the students could not in consequence see the operations. Visitors are always most welcome at operations,

Digitized by Google

and it is to be hoped they always will be so; but there should be no crowding round the table so as to obstruct the view of those who occupy the benches or to inconvenience the operator. It would seem hardly necessary to add that neither visitors nor anyone else should carry on an irrelevant or other conversation during a surgical operation, or in tones sufficiently audible to be heard by the surgeon make remarks of any kind upon the steps of the operation, or describe what has been done on similar occasions by some one else. Silence is asked for during operations, and surely those senior members of the profession privileged to occupy the area should strictly observe the regulation. Example is better than precept, and silence cannot be looked for from young and eager students if a bad example is set them by those older than themselves, who ought to know better.

Drink and Crime.

In charging the grand jury on Monday at Newcastle-upon-Tyne Mr. Justice Grantham said he "doubted very much if there was any city in England with the population of Newcastle which at the present time could present such a clean bill of health to one of Her Majesty's judges when he came down for the purpose of assisting them in the administration of justice. He could not suppose, of course, that Newcastle was free from the vice of intemperance entirely, but it certainly did speak a great deal for the temperate character of the people that no crime which had its origin in drink was to be brought before them." The late Mayor of Newcastle published statistics showing that for its size Newcastle was the most drunken city in England, and these statistics have never been shown to be incorrect. Most people who have gone into the question tell us that drink is the great cause of crime, and there can be no doubt whatever that drink is a great demoralising influence; but is it the chief cause of crime? If so, Liverpool should be ten times more drunken than Newcastle, for there Mr. Justice Collins has to try seven cases of murder and eight cases of manslaughter, while here there are only three criminal cases to be tried—a burglary, a larceny, and an offence under the Criminal Law Amendment Act.

Newcastle-upon-Tyne, Nov. 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

AT the meeting of managers of the Royal Infirmary on Monday the treasurer submitted a statement of the income for the financial year which ended on Sept. 30th. The ordinary income amounted to £31,086, showing an increase of £1400 over the preceding year. The various increases and decreases were specified and satisfaction was expressed that the church collections had increased as the result of the special appeal made to the various ecclesiastical bodies. The average number of patients in hospital had been 711. There had been a considerable decrease in expenditure in several directions, mainly in various articles of food, but also in dressings and medical appliances.

University College, Dundee, and St. Andrews University.

At a meeting of the council of University College, Dundee, held this week, the question of the future relations of the College to St. Andrews University was discussed. It was decided to write to Her Majesty's Commissioners pointing out that the original agreement, which had been submitted to, and approved of by, all the interested parties, and which had been adopted after careful consideration on both sides, had always been regarded by, the College authorities as just and fair. The council were willing to consider any suggestion which might be made by the Commissioners with a view to remove the difficulties which at present existed between the two bodies, and they were prepared to meet the Commissioners or the University Court to discuss anew any proposals which might form the basis of a new agreement.

Stirling Royal Infirmary.

The annual meeting of the subscribers to this institution was held this week. The report showed that the number of in-patients during the year had been 282. The income had been £1106, and the expenditure £1173.

The Edinburgh Obstetrical Society.

This society held its first meeting for the session 1895–96 on Wednesday of last week. Dr. Barbour gave a short valedictory address, and some other communications followed. Dr. Ballantyne (Dalkeith) was elected President in succession to Dr. Barbour.

Notification of Infectious Diseases Act.

An action of a somewhat unusual character has recently been brought against Dr. James Stewart of Maryhill, Glasgow. The pursuer alleged that when he was lying ill in a public lodging-house suffering from pneumonia and under the care of another medical man Dr. Stewart became aware of his illness and notified to the sanitary authorities that he was suffering from small-pox. As a result of this he was removed to Knightswood Hospital, where, he contends, he acquired typhus fever. For the loss of time and personal annoyance and risk he claimed the sum of £200 as damages against Dr. Stewart. The sheriff, however, has dismissed the action without allowing it to go to proof. His lordship remarks that no malice is alleged by the pursuer, and contends that any member of the public, whether a medical man or not, is entitled to give information to the authorities of the existence of any case of infectious disease. The position of the public towards such cases is, according to the sheriff, the same as their relation to any criminal offence. For these and other reasons he decides that the pursuer, even on his own statement, has no valid ground of action against Dr. Stewart. The action having terminated in this fashion, the defender had no opportunity of stating his own position. In a letter in the public prints Dr. Stewart explains that he received a request to call at the lodging-house, where he found the pursuer suffering from typhus fever, and he at once notified the case. The patient was removed to hospital, where at first he was regarded as suffering from malignant small-pox; afterwards, however, the disease was recognised as typhus fever. Dr. Stewart is naturally indignant at the absurd suggestion that he obtruded himself upon the patient for the sake of the small statutory fee payable by the local authorities.

Stranraer Cottage Hospital.

The usefulness of this institution has now been demonstrated by a three years' experience, and the annual report for the present year gives a favourable account of the condition of the hospital from all points of view. The financial statement shows a balance on the right side of the account. Sir Mark Stewart, M.P., is the President of the Hospital Committee.

Medical Preliminary Examination in the Scottish Universities.

The Joint Board of Examiners for the Scottish Universities have issued a statistical report showing the passes and failures in the recent preliminary examinations in arts, science, and medicine in the four universities. The results of the medical preliminary examination are as follows: In Edinburgh University, of 128 candidates 72 passed and 56 failed; in Glasgow University there were 41 passes out of 92 candidates; in Aberdeen University, of 26 candidates 14 proved successful; and in St. Andrews University the entrants numbered 7, of whom 4 passed.

Bacteriological Laboratory in Glasgow.

The health committee of the town council has decided to establish and equip a complete bacteriological department in the sanitary buildings now in course of erection. The laboratory is to be in charge of an expert in bacteriology.

Greenock Eye Infirmary.

At the annual meeting of the trustees on the 14th inst. Dr. Cluckie reported that there had been 3151 patients during the year, an increase over last year of 307. This number included 185 in-patients. Dr. Cluckie expressed the opinion that the eyes of school children were often overtaxed and complained of the action of the School Board officials in bringing pressure to bear on children to attend school when rest had been ordered by the medical adviser. The report by Dr. Robert Fullarton showed a record of 127 cases of diseases of the throat, 71 cases of diseases of the nose, and 542 cases of ear disease. The treasurer's statement for the year gives a balance of £40 in favour of the hospital, the total income being £810 8*s.* 9*d.*

Outbreak of Swine Fever.

A somewhat serious outbreak of swine fever has occurred in the neighbourhood of Greenock. At the instance of an inspector from the Board of Agriculture eighty pigs have been destroyed in one district and sixty in another. It is to be hoped that these vigorous measures will have stamped out the disease.

dents: J. E. Bowes, M.B., C.M.; W. M. Taylor, M.B., C.M.; Kenneth Maclean, M.B., C.M.; H. J. F. Simson, M.B., C.M. Secretaries: J. Brunton Blaikie and Scott Carmichael, M.B., C.M. Chairman of Finance Committee: Edwin Bramwell. Curator of Library: Henry Fowler. Curator of Museum: T. Anderson. Chairman of Public Business Committee: W. T. Ritchie. Editor of Transactions: W. A. G. Alexander, M.B., C.M. Treasurer: J. R. Young. Sub-librarian: A. P. Ormiston.

Nov. 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Regius Professorship of Surgery at Dublin University.

THE appointment of a successor to the late Sir George Porter as Regius Professor of Surgery was delayed for a very long time owing to the fact that the two candidates, Sir William Stokes and Dr. Charles Ball, had each received an equal number of votes from the eight members of the Trinity College Board. The question was referred to the Academic Council, who declared in favour of Dr. Ball, cancelling the objection to his nomination, which had been made on the ground that he filled the office of University Anatomist. The Board met again on Saturday, the 16th, and settled the matter at last by electing Dr. Charles B. Ball Regius Professor of Surgery. Much interest was taken in the result of this election for many reasons, including the fact that the appointment of Sir William Stokes would have entailed his resignation of the Professorship of Surgery at the Royal College of Surgeons, for which last position there would have been many applicants.

The late Dr. Edward Kough.

The death of Dr. Edward Kough, which took place on the 10th inst. at his residence, Albany-grove, Monkstown, is fully recognised as a serious calamity, not alone to society in the district in which he lived, but also to the general public of Monkstown and Blackroch. Dr. Kough, who was a graduate, scholar, and M.A. of the Dublin University, practised originally at Windlesham, Surrey, but has for some years resided near Dublin, filling the position of vice-chairman of the Commission of the Blackroch township. His funeral, which took place on the 14th inst., was very largely attended.

Dublin University Experimental Science Association.

Mr. A. C. O'Sullivan, M.A., F.T.C.D., the recently appointed University Lecturer on Pathology, delivered the opening address at the inaugural meeting of the association held on Monday evening, the 11th inst., the Provost occupying the chair. He chose as his subject "Scientific Education" and in a short paper advocated strongly the importance of early training in practical experimental work as distinguished from training by books.

Mater Misericordiæ Hospital.

The metal anastomosis button introduced into surgery by Dr. Murphy of Chicago has not apparently commended itself very highly to Dublin surgeons, for although Dr. Murphy was good enough to demonstrate its action on the dead subject here during the summer, no case in which it has been employed has as yet been reported in Ireland. The following note is therefore of interest. A delicate woman aged fifty-five was recently admitted to the Mater Misericordiæ Hospital under the care of Mr. Coppinger suffering from pain and tumour in the right iliac region. An exploratory incision was made and the presence of a narrow stricture at the commencement of the ascending colon discovered. On account of the patient's general condition immediate excision of the diseased intestine was considered inadvisable. On the other hand, the obstruction being situated beyond the ilio-cæcal valve rendered the case an apparently suitable one for the use of some rapid method of relieving the symptoms. A button of large size and constructed of aluminium was accordingly employed, and a lateral anastomosis of the ileum with the transverse colon established without difficulty or delay. The operation took place on Tuesday, the 12th; there was no subsequent shock or elevation of temperature, and the patient now seems well and expresses herself as much relieved. The bowel has been emptied twice, but there has been no appearance of the button up to this (the eighth) day. The case is novel and interesting, for as the intestine was not closed the button may unfortunately drop back into the ascending colon and become engaged in the stricture at its commencement or may pass into the ileum and be thus carried to the stricture.

Belfast Royal Hospital.

The annual meeting of the supporters of the Belfast Royal Hospital was held on Monday, Nov. 18th. From the report I learn that the number of patients treated in the hospital during the year amounted to 2655, while during the same period there were 22,956 extern patients. The expenditure for the year has been £9073 18*s.* 6*d.*, and the receipts £8731 16*s.* 8*d.* The expenditure has, therefore, exceeded the receipts by £342 1*s.* 10*d.*, but as there was a balance in favour of the hospital at the end of the preceding year the actual debt at the end of this year is £142 4*s.* 10*d.* Attention is again called to the increase in the subscriptions of the working classes. From the medical and surgical staff report I learn that of the cases admitted into the wards 968 were medical and 1097 surgical, while in the extern department 4831 were medical and 16,173 surgical. One hundred and thirty-eight students attended in the wards for clinical instruction during the winter and one hundred and ten during the summer session. Special reference was made at the meeting to the great loss sustained by the hospital by the death of Dr. Ross. One of the speakers drew attention to the fact that the item of wines and spirits and aerated waters in their expenditure was £137 19*s.* 8*d.*, and that the sum spent in medicine and instruments was £1108, or, in other words, that the cost of wines, spirits, and aerated waters amounted to one-eighth, or 2*s.* 6*d.* in the £, of that of medicines and instruments. The secretary of the medical staff, in reply, stated that in round numbers about £100 was spent in spirits and wine, and he believed that was the smallest sum spent in that way by any hospital, taking the numbers into account, in the United Kingdom. The sum was gradually diminishing; thus, in the previous year it was £150, and when he joined the staff first the stimulants cost £435 per annum. The actual amount spent in aerated waters, whisky, wine, beer, and everything of that kind amounted to about ½*d.* per day per patient in that institution. Stimulants were used only in critical and severe cases.

Belfast Medical Students' Association.

At the first general meeting of this society, held on Nov. 15th, Dr. Donnan, who was in the chair, suggested that a letter of sympathy should be sent to Mrs. Ross in reference to the death of her husband, Dr. Ross. This was unanimously approved of. The following officers were elected for this session:—President: Dr. Magowan. Vice-presidents: Dr. Drummond, Dr. Fullerton, and Dr. Donnan. Hon. Secretary: W. A. Rice, B.A. Assistant Secretary: R. Hilton. Treasurer: O. E. McCutcheon, B.A. Committee: J. McCully, A. B. McMaster, M. L. Rowan, G. Stevenson, Miss Collier, R. J. Johnstone, B.A., A. Knight, D. Brown, Miss Tate, and G. Anderson.

Changes in the Belfast Royal Hospital Staff.

The death of Dr. Ross, senior physician to the Belfast Royal Hospital, will occasion considerable changes in the staff. Dr. Strafford Smith will have no opposition in being promoted from the assistant physicianship, and it is thought Dr. W. Calwell, who for the past two years has discharged most effectively and to the entire satisfaction of the whole staff the duties of registrar, will be appointed assistant physician. There will be a good many candidates for the registrarship—a post which is in the gift of the staff.

Lunatics in the Newry Workhouse.

At a meeting of the Newry guardians, held on Nov. 16th, a report was read from Mr. O'Farrel, Inspector of Lunatics and Commissioner of Control, Dublin, in reference to his inspection of the workhouse on Nov. 2nd, 1885, in which he states that the greatest blot on the arrangements is the survival of those cold and cheerless idiot cells, which have been repeatedly condemned since 1843. Any patient, the inspector says, who needs a separate cell is not a fit subject for detention in a workhouse, and he or she should be removed, not as a dangerous lunatic, but on a house form to the lunatic asylum of the district. As this question of the suitability of workhouses for the treatment of lunatics is so constantly being discussed at present it is felt by many that a commission should be appointed to inquire into the whole matter.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The late Dr. Dujardin-Beaumetz's Laboratory.

THE therapeutical laboratory attached to the wards of the above-named distinguished therapeutist will, at the request of Dr. Albert Robin, be forthwith transferred from the Hôpital Cochin to the Hôpital de la Pitié. This transference includes the annual subvention of 2000 francs allowed by the Municipal Council.

The Diagnosis of Infectious Diseases.

The Municipal Council of Paris has decreed that the diagnosis of diseases caused by the invasion of known micro-organisms shall henceforth be undertaken by the bacteriological laboratory of the city, any practitioner plying his art in the capital or in the Department of the Seine being entitled to send specimens for the purpose.

The Weight Development of Prematurely Born Children.

In a thesis for the M.D. degree of the Paris Faculty (July, 1895) Dr. Potel supplies some instructive information on this subject. His researches bear upon 173 infants, born between the periods of six and a half to eight months of gestation, and who left the Paris Maternity alive and well after an average sojourn for the six-and-a-half month children of eighty-two days and for the eight-month children of twenty-eight days. Of the fifty-six children born at six months and a half eleven survived (mortality 80·4 per cent.). The average daily gain in weight was 9·4 grammes. Of 131 infants born at seven months 41·9 per cent. survived, the average daily gain of weight being 11·5 grammes. Of 53 children born at seven months and a half 69·9 per cent. survived, and the average daily gain of body weight was 13·8 grammes. Finally, of 110 children born at eight months 64·5 per cent. survived, and the average daily weight-gain was 22·8 grammes. The following table shows the average body weight at birth :—

1408	grammes	at	6½	months.
1700	,,	,,	7	,,
1900	,,	,,	7½	,,
2150	,,	,,	8	,,

The loss in weight during the first three days of extra-uterine existence is not more marked than in infants born at term, but it constitutes a serious event in these prematurely-born beings, for restoration to the original weight is a more prolonged business, and it is precisely during this period that the mortality is the heaviest. The offspring of parents free from hereditary taint are, however, more resisting. The gain in weight begins later and proceeds at a slower pace the more prematurely the child is born. Thus in six-and-a-half-month children a gain in weight is frequently noted only after the first fortnight. The nearer to full term the infant is born the closer does the progress in weight approach that of the normal child. The artificial means employed to sustain vitality in the prematurely born—incubators, sterilised milk, "gavage"—enables us to save many a life.

Foreign Students and the Paris Faculty.

The *Bulletin Médical* is responsible for a piece of information that will prove unpleasant reading to foreign students who, wishing to begin their medical curriculum at the Paris Faculty without having to pass the examinations for the *baccalauréat* (these being the equivalent of our preliminary or matriculation examinations) ask for the *équivalence*, or, in other words, to be excused the *baccalauréat*. It is notorious that many foreigners—principally Russians, Roumanians, and Greeks — have hitherto been granted the *équivalence* on the strength of having undergone in their own country examinations in general education which cannot compare as a test with the French *baccalauréat*. A special commission appointed some months ago by the Minister of Public Instruction has just reported on the question. All students asking for the coveted *équivalence* have accordingly been told that this indulgence can only be granted in view of their extra curriculum being pursued at a provincial faculty. Interviewed on the subject, Professor Brouardel, the Dean of the Paris Faculty, is said to have remarked that such an extreme measure has been forced on the authorities by circumstances. He states that the faculty is organised for the education of only 3000 students, whereas the number of students is actually 6300, of whom a fifth last year were foreigners. Subjects for dissection are becoming scarce, and overcrowding is interfering materially with the efficiency of the teaching. In the interest of native students the measure just taken was inevitable. The new regulation means that any Englishman or other foreigner unprovided with a diploma in medicine who may be desirous of studying in the Paris Faculty must, despite his matriculation or preliminary examinations passed in his native country, either obtain his *baccalauréat* or be content to pursue his studies at a provincial faculty.

Nov. 19th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Etiology of Paralysis.

AN interesting lecture on the Etiology of Paralysis was delivered by Dr. Hirschl at a meeting of the Society for the Study of Neurology and Mental Diseases. His observations were made on 200 cases, in 50 per cent. of which the existence of syphilis was ascertained, in 25 per cent. it was regarded as probable, in 12 cases there were objective symptoms of syphilis, and in 19 per cent. the exciting cause was not discernible. 175 men affected with paralysis procreated 233 living children, of whom 154 died at an early age; the wives miscarried 106 times. The uniformity of the appearances of the disease, which was represented by diffuse interstitial encephalitis and by peri-encephalitis, suggested an etiological connexion, and the fact that all factors except syphilis were excluded pointed to syphilis as being the primary cause. Dr. Hirschl laid much stress upon the anatomical conditions in paralysis and their relation to the pathology of syphilis. The anatomical lesion of paralysis is, as a rule, described as cortical encephalitis beginning with chronic atrophy of the cortex. Some symptoms of paralysis occur only in tabes, a disease which is of syphilitic origin. Immobility of the pupils is a symptom met with after syphilis of the brain, and may also be observed in paralysis and in atrophy of the optic nerve. In some cases mercurial treatment produces an improvement. Paralysis is, therefore, a result of syphilis just as gumma is, and the occurrence of paralysis in children without antecedent primary disease resembles the occurrence of tertiary symptoms without antecedent primary and secondary manifestations.

The Sanitary Report for 1892.

According to the report of the Statistical Commission the number of Austrian hospitals in 1892 amounted to 625, with 38,496 beds, and 371,811 patients were admitted. Of these, 85·9 per cent. were discharged recovered or improved, 5·1 per cent. were incurable, and 9 per cent. died. The report mentions 27,892 cases of syphilis and 18,879 cases of tuberculosis. In twenty-eight public and six private lunatic asylums there were 17,936 patients in 1892, against 16,583 in 1891. Of these, 8·2 per cent. recovered, 19·8 per cent. were incurable, and 10·1 per cent. died; 14·2 per cent. suffered from mania, 10·7 per cent. from melancholia, 30 per cent. from paranoia, 26·6 per cent. from idiocy, 10·6 per cent. from mental disorder with paralysis, and 7·9 per cent. from mental disorder with epilepsy; 56·4 per cent. were unmarried, 36 per cent. married, and 7·6 per cent. widowed. As to religion, 92·4 per cent. were Roman Catholics, 1·8 per cent. Protestants, and 4·9 per cent. Jews. 10,013 children were admitted to the foundling hospitals, and of these 6·02 per cent. died. There were 1543 persons in seventeen asylums for the deaf and dumb. The number of institutions for the blind amounted to ten, with 795 inmates, of whom 14·9 per cent. had been born blind. Cretins numbered 17,541. For each 100,000 of the population there are 78 lunatics, 119 deaf-mutes, 66 blind persons, and 74 cretins. The report also mentions 239 bathing institutions, which have been resorted to by 250,692 persons. There were 4082 qualified and 2472 unqualified medical practitioners and 1531 surgeons of the old school. There were 3042 deaths per 100,000 of the population, the highest mortality having been registered in Galicia. Of 100,000 cases of death, 26 resulted from small-pox, 38 from measles, 58 from scarlet fever, 57 from enteric fever, 77 from dysentery, 72 from whooping-cough, and 120

Digitized by Google

from diphtheria. Cholera caused 125 deaths, of which 120 occurred in Galicia, 3 in Lower Austria, and 2 in Styria.

Dissolution of the Municipality of Vienna.

Dr. Lueger, the famous leader of the Anti-Jewish Party, who, as I have already reported, was elected mayor, has not been acknowledged by the Crown. A second election having yielded the same result, the Government dissolved the municipality and appointed an official to administer its functions. Among the medical profession this fact has caused general sstisfaction, Dr. Lueger, who is a lawyer, being very unfavourably disposed towards medical men, in proof of which I may quote his well-known saying: "Any woman who gathers herbs is to be preferred to the medical men, for they poison people with drugs."

The Relation between Recent Syphilis and Jaundice.

Professor Neumann has contributed to the *Medicinische Presse* an article on the occurrence of jaundice in cases of recent syphilis. French authors, such as Gubler, have supposed jaundice appearing in recent syphilis to be due to an exanthem of the intestine and the biliary passages. During the last three years Professor Neumann has observed fourteen cases; in eight of them jaundice and exanthem occurred at the same time, and in three cases after the eruption. One of these patients died, and post-mortem examination showed numerous prominences of a yellowish colour on the surface of the liver; the peripheral parts of the lobules were green, and the central parts reddish. He believed jaundice in these cases to be due to changes in the wall of the vessels.

Medical Advertising.

Last week the Medical Chamber summoned before it the gentlemen who continue their advertising in the lay press in spite of the fact that it has been declared dishonourable in a professional sense. Seventeen delinquents attended in response to the summons and were reprimanded by the president, but appealed to the Government, which will now decide the question.

Cholera in Galicia.

During last week 66 cases of cholera with 41 deaths were reported from the districts of Czortkow, Husiatyn, Kamionka, Trembowla, and Tarnopol, making a total of 303 cases with 192 deaths since the commencement of the outbreak. In the preceding week there were 57 cases and 32 deaths.

Nov. 17th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

An Academico-Clinical Odyssey.

DR. BACCELLI, in his capacity of Minister of Public Instruction, has just made a tour of some of the minor seats of learning in the Peninsula, beginning with Ravenna, which, though not an academic town, is in its monuments and its Biblioteca Classense full of academic interest, and thence proceeding to Ferrara and Modena, at both of which universities he made a minute examination of their teaching, particularly their clinical resources, and addressed their professorial and undergraduate *personnel* in words of hope and encouragement. His countrymen delight to regard his Excellency as an ideal Education Minister, for not only are his attainments of the highest academic order, extending to an enlightened love of the classics, but he interests himself in fine art and in physical development, and, as a primary condition of all healthy and sound work, in the hygienic amelioration of school and college, private dwelling and public institution. At Ravenna he had much of practical advice to give as to its water-supply and the *risanamento* of its neighbourhood; at Ferrara he had not only to expatiate on the sanitary defects of the sombre mediæval town, but also on the rehabilitation of the University and the reinforcement of its teaching power, while at Modena an inspection of the backward state of the laboratories and clinical wards drew from him a promise to enlist Government support in their behalf. "Minor seats of learning" these historic capitals doubtless are, but they are not on that account without their honourable record in the annals of the healing art, and Dr. Baccelli was able, from his great command of medical history, to enumerate their contributions to the common fund of professional knowledge. Modena, for example, could boast of the epoch-making Francesco Torti, whose classic work on "Febres Periodicæ Perniciosæ" was the first to put their description and therapeutics on a rational and truly Hippocratic basis. It was through him that cinchona bark in malaria scored its first decisive victory. Other names (Ramazzini, for instance) were given by Modena to medicine, and yet more hardly less distinguished might still be added if the resources of the school were equal to the educational demands on them. But this is a perennial subject of complaint in Italy, by no one more eloquently set forth than by Professor Angelo Celli, whose inaugural address at the opening of our academic year put in striking relief the inferiority of even the Roman school to the humblest of its class in the English provinces.

A Touching Tribute to the "Martyr Nurse."

Readers of THE LANCET of Nov. 24th, 1894, can hardly have forgotten the thrill of horror with which, just a year ago, the assassination of Suor Agostina in the Santo Spirito was received. On the 13th inst. a tablet was unveiled in her memory in the Cappella del Crocefisso in the church attached to the hospital. It is surmounted by a medallion presenting a finely modelled bust in bas-relief of the Sister, and bears the following inscription:—

D. O. M.
A Maria Agostina
Suora di Carità di S. Vincenzo De Paoli
Angelo d'innocenza, di pietà, d'amore
La cui vita fu tutto un sacrifizio
La cui morte un martirio
Uccisa per odio al sacro abito
Con sette pugnalate da mano assassina
Nell'Ospedale di S. Spirito in Sassia
Il dì 13 Novembre 1894
Da tutta Roma compianta
Seguita da immenso popolo alla tomba
Il comitato parrocchiale di S. Pietro
in Vaticano
a perenne memoria della martire
della carità, del dovere
P.

(To God Allgood and Almighty. To Maria Agostina, sister of Charity of Saint Vincent De Paul, an angel of innocence, of piety, of love, whose life was all one sacrifice, whose death was a martyrdom, slain as she was, through hatred to the holy uniform, with seven stabs by a murderer's hand, in the hospital of the S. Spirito in Sassia, 13th November, 1894, lamented by universal Rome, followed by an immense crowd to the grave, the parochial committee of S. Peter on the Vatican have placed this monument to the undying memory of the martyr to love and duty.) This admirable specimen of epigraphy, showing as it does how modern Italian lends itself almost as felicitously as ancient Latin to the literature of "storied urn and animated bust," sins in one particular and one only, in its reference to the object that directed the "mano assassina." That object was not "odio al sacro abito" (hatred to the holy uniform), but, as THE LANCET pointed out at the time, resentment on the part of the murderer (Romanelli) against the sister for having reported him for bad conduct. The Padre Ronzina, who composed the inscription in the presence of the whole *personnel* of the hospital, including all the nuns directly or indirectly employed in it, and who acted as spokesman at the unveiling, cannot but have been misinformed of the circumstances under which Suor Agostina was done to death.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera Intelligence.

DURING the past seven days there have been 83 new cases admitted into the twelve ambulance hospitals, while the deaths have numbered 72 in hospitals and 85 in private houses in the villages. The ignorant peasants have a rooted objection to the fresh air and cleanliness of hospital huts under English superintendence, and do their best to hide their sick and make difficult all sanitary measures. Five cases have been reported from one newly attacked hamlet of 300 inhabitants, the first case having been imported from a neighbouring village where cholera existed for a fortnight, but is now apparently no longer present. The disease has also appeared in a village half-way between Damietta and Mansoura, probably from being in free intercourse by canal

Digitized by Google

with an infected village. Three fresh importations have taken place at the inspection stations outside Mansoura. But in spite of these new attacks the disease is still confined to the same districts as before, and the measures for dealing with it when discovered continue, so far, to be wonderfully successful, and the disease is still about 100 miles distant from Cairo. Some experiments have been made by Dr. Kauffmann to test the virulence of this comma bacillus. In the first series the guinea-pigs became slightly ill after being injected, but did not die. Since then a guinea-pig has been injected with an extra-strong culture, prepared with unusual care, and he died in twenty hours.

Precautions in Infected Districts.

Sixteen inspection stations on the Nile and on the principal canals are now in very good working order and are yielding excellent results. Besides these there are eighteen medical inspection stations for land traffic dotted about the various villages. All travellers from the infected area are still examined at their destination by a medical man specially told off for this purpose, and then they are visited for the five ensuing days at their new address in order to be certain that they remain in good health. The bulk of the sanitary *personnel* is in the infected area, but, of course, if the disease spreads to any of the chief towns, such as Mansoura or Zagazig, some change will have to be made and a fresh disposition of the forces may be required. The native officials are all quite willing to work, but are incapable of initiating any reform, though they can be made to do excellent work by any energetic Englishman who understands their incapacity and their language. It is significant that we hear nothing just now of the unpopularity of the English in Egypt. On the contrary, seven millions of people are content to look on and do nothing, while less than a dozen Englishmen are wrestling to keep them free from cholera.

General Precautions in Egypt.

The tourists who are already coming here in considerable numbers will find this country preternaturally clean this winter, for during the last month a general scavenging and whitewashing have taken place, and every Mudir has trembled in his shoes lest his province should be weighed in the balance of hygiene and be found wanting. Especial attention has naturally been paid to the chief towns of the Delta, but in Cairo itself a sanitary commission has been working hard to deal with all matters of pressing need. The streets have never been so clean before, and the sweepings, instead of being thrown into a disused canal which may some day be built upon, are now taken outside the town to fill up a large pond. The water company has undertaken to put up hydrants for the supply of pure water gratis in the poorest quarters, such as Boulak and Old Cairo, where cholera would be most likely to appear. Sites are being chosen for much-needed public latrines, and many smaller improvements have been already effected. Any true sanitarian, of course, wishes his work to be permanent, but it is the tendency of the financial official mind to lavish money when in presence of an epidemic, but to jealously tighten the purse-strings the moment the danger no longer threatens. The municipality of Alexandria has voted £4000 for the sanitation of the city, and £300 have been granted to improve the laboratory of the sanitary inspector, who is now building a house for the installation of his zoological pets, and arranging rooms for micro-photography. The city has been very well cleaned superficially, and an artesian well is being sunk, 100 ft. deep, for supplying gratis water to the poor.

Water-supply.

A concession for the supply of water to the three important towns of Tantah, Zagazig, and Mansoura has been given by the Government to a rich company, who have already found most excellent soft water by a boring 100 ft. deep on an estate of thirty-five acres outside the town of Tantah. From this free fountains are now running for two hours a day.

Quarantine against Egypt.

It is felt here that visitors will be kept away not so much by the fear of cholera as by the dread that they may not be able to leave this country when they wish to do so. At present there is no quarantine against Egypt in any country excepting Greece.

Cairo, Nov. 13th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Further Developments in the "Dean Case."

CONSIDERABLE sensation has been caused by recent proceedings in connexion with the remarkable case of alleged poisoning at Sydney, a summary of which was given in THE LANCET of Aug. 17th last. In answer to a question in the Legislative Council, the Attorney-General said that Sir Julian Salomons, counsel for the prosecution in the case, had informed him that Mr. Meagher, solicitor for the defence, had admitted that he knew absolutely that Dean was guilty, as the latter had confessed that he had administered both arsenic and strychnine together to make more certain of poisoning his wife, and that the druggist who sold the poisons had never been asked, although he gave evidence, whether he sold the poisons. Mr. Meagher vehemently denies that he made any such admission to Sir Julian Salomons, whom he accuses of mental aberration, while his partner more than insinuates that the whole story is a pure invention. All the principals in the affair are prominent politicians, and, with a view probably of removing the case from the political sphere, the last development is that Dean and his solicitors, Messrs. Meagher and Crick, have been arrested on a charge of conspiring to defeat the ends of justice.

Dispute at the Adelaide Hospital.

For some months past the columns of the Adelaide papers have been deluged with correspondence and articles on a comparatively trivial dispute about a nurse's appointment at the Adelaide Hospital. About eight months ago the board of management made an appointment to the post of night superintendent of nurses on the recommendation of Dr. Perks, the medical superintendent, who said that a Miss Gordon was the only nurse in the hospital suitable for the position. This opinion was intended by the superintendent to be confidential, but it got into the press, and also a statement that the lady recommended was a relative of a public official, whose sanction to any appointment or dismissal by the board is required. The nurses complained to the board in somewhat forcible and ill-advised terms; the press took the matter up and clamoured for an independent inquiry, and finally a Royal Commission was appointed. In the meantime the nurses themselves, with two exceptions, withdrew from their position and apologised to the board, Dr. Perks giving the assurance that no reflection was cast on their capabilities. The Commission practically exonerated everyone, and suggested a *status quo ante*. The board, however, declined to reinstate the two nurses who had not apologised, as that would be subversive of discipline. However, the board had to submit in the case of one of them, as her suspension had not been sanctioned by the Chief Secretary. On the other hand, as the other nurse's appointment had never been confirmed by the Chief Secretary the board declined to reappoint her. So the matter stands, and will probably end. A special meeting of the South Australian Branch of the British Medical Association was held recently to consider the position, and it was unanimously resolved that the meeting entirely approved of the attitude adopted by the board of management during the recent trouble with the nursing staff; and placed on record its high appreciation of the valuable services of Dr. Perks in his position as medical superintendent, and its strongest sympathy with him in the gross and unfounded charges made against him in the evidence of certain witnesses before the Royal Commission.

Election of the Staff of the Women's Hospital, Melbourne.

The medical staff of the Women's Hospital is elected every four years by the subscribers to the hospital on the same plan as in the case of the Melbourne Hospital, the election taking place a month subsequently. The election does not create so much public interest, however, and is conducted more quietly. On this occasion some new offices were competed for. Many years ago the institution was essentially a lying-in hospital, and was so designated, and the staff consisted of four honorary medical officers and a resident officer. Out-patients suffering from pelvic disease, however, were seen, and a few beds were reserved for such cases. With the progress of gynæcology more and more cases of diseases peculiar to women were found to demand operative treatment as

Digitized by Google

in-patients, and the hospital was enlarged by building a practically new hospital in the same grounds, devoted solely to midwifery cases. A new staff, honorary and resident, was elected to take charge of the midwifery department, the old staff retaining charge of what was now termed the infirmary department of the Women's Hospital. The latter department has again been found inadequate, and a new wing is in process of construction, and four new positions of out-patient surgeons have been made, with a view of lightening the work of the in-patient staff. The result of the election held on Sept. 30th was as follows:—

INFIRMARY DEPARTMENT.

Dr. O'Sullivan	851	Mr. Dunbar Hooper	749
Dr. Adam	845	Dr. Rowan	534
Dr. F. Meyer	834		

MIDWIFERY DEPARTMENT.

Dr. Mackay	730	Dr. Loosli	549
Dr. Downie	631	Dr. Martell	489
Dr. Nyulasy	589	Mr. Branson	371
Mr. Cuscaden	553	Mr. Wheeler	360

FOR OUT-PATIENTS.

Mr. Morton	870	Dr. Joske	396
Dr. Horne	858	Mr. Lynch	390
Mr. Anderson	722	Mr. Clayton	352
Dr. Fetherston	697		

The first four were elected in each case.

Laparotomy for Intussusception in very young Children.

In a paper read before the New South Wales Branch of the British Medical Association Mr. C. P. B. Clubbe detailed seven cases of intussusception in children under six months old, all operated on, with four recoveries, a percentage that compares very favourably indeed with those previously recorded, and has led Mr. Clubbe to conclude that the operation, which is easy, should be performed early in all cases, however young the child, if rectal injection or inflation fails.

Appointments.

Dr. A. Jarvie Hood has been elected physician to the Sydney Hospital in place of the late Dr. Huxtable. Dr. Gordon MacLeod has been appointed assistant ophthalmic surgeon at the Sydney Hospital. Dr. W. H. Goode has been appointed official visitor to the Hospitals for the Insane at Gladesville and Callan Park, and Dr. Alfred Shewen as omcial visitor to the Hospital for the Insane at Paramatta.

Obituary.

HENRY GRACE, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.

MR. HENRY GRACE died very suddenly last week. On Nov. 11th, in the best of spirits, he left Kingswood for Honiton, where he intended to have a few days' shooting with an old schoolfellow. On the 13th, whilst shooting, he had a stroke of paralysis, and expired before any of his family had time to reach him. Mr. Grace was the eldest member of the well-known Grace family and was born at Downend in 1833. He was educated at the Bristol Medical School, and after taking the London qualifications he settled in practice at Kingswood. Mr. Grace was a typical country surgeon—his duty to the sick was his first consideration, and in his large practice he was held in the highest esteem. This practice was probably the largest country practice in Gloucestershire; in addition to being medical officer of health of Kingswood and surgeon to the Stapleton Workhouse, he was medical officer to most of the local friendly societies. He took a keen interest in all that concerned the welfare of the neighbourhood. Like other members of the family, he was an ardent sportsman, and in his younger days earned some distinction as a cricketer. He was interred last Saturday at Downend Churchyard in the presence of a large concourse of people. The "Doctor," as he was generally termed, will be sadly missed at Kingswood, and much sympathy is felt for his widow and family, which consists of four daughters, three of whom have married members of the profession, and one son, who is in practice in Derbyshire.

RICHARD ROSS, M.D. ST. AND., L.R.C.S. IREL.

THE announcement of the death of one of the oldest and most respected of the medical practitioners of Belfast, Dr. Richard Ross, which took place at his residence on Wednesday morning, Nov. 13th, was received with great regret by a numerous circle of friends. Dr. Ross's death came as a great surprise to the people of Belfast, as, although he was sixty-eight years old, he had been busy at work almost up to a week before his decease. It would appear that on the afternoon of Nov. 5th he was seized with sudden weakness while out, and on the following day a rheumatic attack with heart complications developed, which terminated suddenly in death from heart failure on Nov. 13th. Dr. Ross was born in county Monaghan and was the son of a Presbyterian clergyman. Through the influence of an uncle who was a physician in Rostrevor, with whom he spent a considerable portion of his boyhood, Dr. Ross decided to enter the medical profession and went to study in Dublin. He became qualified in 1848 as a Licentiate of the Royal College of Surgeons of Ireland, and in 1850 he took the degree of M.D. at St. Andrews University, having previously become a Licentiate in Midwifery of the Coombe Hospital, Dublin. When a student he was a clinical assistant at the Meath Hospital, Dublin, and soon after completing his college course he went to the west of Ireland, where he had considerable experience in dealing with an epidemic of cholera. In the year 1850 he commenced practice in Belfast, and he was one of the first five medical gentlemen elected as dispensary medical officers for Belfast under the present Poor-law system. This post he held for about twenty years, when he retired from the office on being elected physician to the Belfast Royal Hospital, an appointment which he held until the time of his death, up to which he was not only senior physician but also the senior member of the entire staff. He was also consulting physician to the Hospital for Diseases of the Skin and to the Hospital for Consumption and Diseases of the Chest, and he was the local consulting physician in Belfast for some of the best-known life assurance companies. He was one of the oldest members and also a former president of the Ulster Medical Society. Dr. Ross for a lengthened period had one of the very best medical practices in Belfast; his extremely kind disposition and his wonderful skill in prescribing caused him to be regarded by his patients not only as an able physician but also as a beloved personal friend. He was an extreme favourite with the members of his own profession, and many of them now in prominent positions in Belfast recall with the utmost gratitude his kindly advice and assistance in their early career. Dr. Ross was a man who never did a dishonourable action or said an unkind word. He leaves a widow, a daughter, and a son (now a clergyman of the Church of Ireland) to mourn their loss. His brother, the late David Ross, Q.C., who was Recorder for Belfast and county court judge for county Antrim, in his will left the residue of his estate to his brother Richard (Dr. Ross), "to whose wonderful kindness and aid when they required it he and his other brothers owed so much."

HUGH LANE, M.R.C.S. ENG., L.R.C.P. EDIN.

MR. HUGH LANE, a well-known and respected Bath practitioner, died at his residence in Bush-street on Thursday, Nov. 14th. He contracted diphtheria, and this terminated fatally after a short illness. The deceased received his medical education at Guy's Hospital, and became L.R.C.P. Edin. in 1882 and M.R.C.S. Eng. in 1883. He held the appointments of honorary medical officer to the Royal United Hospital, Bath, and physician to the Eastern Dispensary, Bath.

PITHECANTHROPUS ERECTUS.—A special meeting of the Anthropological Institute will be held on Monday, Nov. 25th, at 8.30 P.M., at 3, Hanover-square, when Dr. Dubois of the Netherland Indian Army will exhibit the curious skull and bones found by him in Java, regarding which opinions differ as to whether they belonged to a man or an ape.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The second meeting of the session was held in the medical library of University College, Bristol, on Nov. 13th, Mr. A. W. Prichard being in the chair. Mr. Morton showed a patient with a Cyst of the Antrum, and a patient with sarcoma of the superior maxillary bone who had been treated by injections of erysipelas toxine.—Dr. J. Michell Clarke read a paper on Huntington's Chorea and Senile Chorea, and exhibited a case of the former affection.—Dr. F. H. Edgeworth showed a series of lantern slides in connexion with cases of Exophthalmic Goitre.

Medical News.

UNIVERSITY OF LONDON.—The following candidates passed the M.B. examination in October:—

FIRST DIVISION.

Abrahams, Bertram Louis, B.Sc., University College.
Barnard, Harold Leslie, London Hospital.
Blake, Victor John, University College.
Brook, Sydney Wilkinson, Owens College and Manchester Royal Infirmary.
Bull, Stanley Arthur, Westminster Hospital.
Cook, Albert Ruskin, B.Sc., Cambridge University and St. Bartholomew's Hospital.
Cook, John Howard, University College.
Crookshank, Francis Graham, University College.
Despard, Rosina Clara, London School of Medicine for Women.
Dimsey, Alfred, University College.
Every-Clayton, Leopold E. V., Guy's and London Fever Hospitals.
Gillies, Sinclair, St. Bartholomew's Hospital.
Handley, William Sampson, Guy's Hospital.
Hopton, Ralph, Yorkshire College.
Playfair, Ernest, King's College.
Pugh, William Thomas Gordon, Middlesex Hospital.
Rodocanachi, Amb. John, B.Sc., University College.
Salter, Alfred, Guy's Hospital.
Shaw, Harold Batty, University College.
Sowry, George Herbert, St. Bartholomew's Hospital.
Thomas, Thomas Morrell, Guy's Hospital.
Walton, Herbert James, St. Bartholomew's Hospital.

SECOND DIVISION.

Allan, Edward Buller, University College.
Belcher, James Arthur, University College.
Blenkinsop, Frederick Linton, University College.
Bodman, John Hervey, University College, Bristol, and St. Bartholomew's Hospital.
Brown, Joseph Norwood, University College.
Byrne, Peter Kevin, B.A., University College.
Carter, Felix Bolton, University College.
Coleman, James Jordan, Guy's Hospital.
Coutts, Francis James, University College.
Crace-Calvert, George Alfred, St. Bartholomew's Hospital.
De Segundo, Charles Sempill, St. Bartholomew's Hospital.
De Steiger, Adèle Isabella, London School of Medicine and Royal Free Hospital.
Dove, Percy William, St. Bartholomew's Hospital.
Eastes, George Leslie, B.Sc., Guy's Hospital.
Edmunds, Percy James, B.Sc., University College.
Ferraby, Henry Percival, Guy's Hospital.
Gibbons, Arthur Philip, London Hospital.
Gurney, Alexander Cecil, St. Bartholomew's Hospital.
Hardenberg, Edward Fras. H., Guy's Hospital.
Hardman, Richard Smith, Owens College and Manchester Royal Infirmary.
Harnett, Charles John, Guy's Hospital.
Haylett, Peter Henry, Guy's Hospital.
Hora, Julian, Guy's Hospital.
Hull, Charlotte Elizabeth, London School of Medicine and Royal Free Hospital.
Hunnard, Arthur, University College.
Hunt, Tom Harold, Owens and Yorkshire Colleges.
Jenkins, Arthur William, University College.
Jewell, William Henry, Guy's Hospital.
Kingsford, Bertram Harold, St. Thomas's Hospital.
Kirton, Reginald Gower, London Hospital.
Knight, Ernest, Owens College and Manchester Royal Infirmary.
Miskin, Ernest, St. Thomas's Hospital.
Nicholson, Thos. Goddard, B.Sc., St. Thomas's Hospital.
O'Hea, James Patrick, St. Bartholomew's Hospital.
Pearson, Maurice Grey, B.Sc., St. Bartholomew's Hospital.
Scharlieb, Herbert John, University College.
Schofield, Samuel Robert, University College.
Sinigar, Harry, Mason College.
Smellie, John Clementson, St. Mary Hospital.
Smith, Frank Addinsell, St. Bartholomew's Hospital.
Spillane, James Charles, London Hospital.
Stoney, Florence Ada, London School of Medicine for Women.
Traill-Christie, Margaret Marion, London School of Medicine and Royal Free Hospital.
Vellacott, Philip Northcott, Guy's Hospital.
Wilks, Morris, University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination in Anatomy and Physiology for the Diploma of Fellow at a meeting of the Board of Examiners on Thursday, Nov. 14th, viz.:—

Charles James Heaton, L.R.C.P. Lond., M.R.C.S. Eng., St. George's Hospital; Charles Ryall, L.R.C.P. Lond., M.R.C.S. Eng., Westminster Hospital and King's College, London; Richard Truman FitzHugh and Arthur John Cleveland, Guy's Hospital; Alexander Gordon Wilson and George Hutcheson, London Hospital; Avery Wynn Dickson, St. Bartholomew's Hospital; Sidney Herbert Berry, Charing-cross and St. Bartholomew's Hospitals. Eight gentlemen were referred for six months.

ROYAL COLLEGE OF PHYSICIANS OF DUBLIN.—The following gentlemen have passed the examination for the Conjoint Diploma in State Medicine:—

E. G. Annis, M.R.C.S. Eng., G. W. Dawson, L.R.C.P. and S.I., W. J. Greer, F.R.C.S.I., J. J. Goodlatte Murray, L.R.C.P. and S. Edin.

FOREIGN UNIVERSITY INTELLIGENCE.—*Buda-Pesth:* Dr. L. Török has been recognised as *privat docent* in Dermatology.—*Giessen:* Dr. Strahl of Marburg has been appointed to the chair of Anatomy in succession to Dr. Bonnet.—*Freiburg (Baden)*: Dr. Gaupp and Dr. Nagel have been recognised as *privat docenten* in Anatomy and Physiology respectively.—*Heidelberg:* Dr. Ernst Göppert has been recognised as *privat docent* in Anatomy. A Dental Institute has been established under the direction of Dr. Jung.—*Prague (German University):* Dr. J. Gad of Berlin has been appointed to the chair of Physiology in succession to Dr. Hering.—*Strassburg:* Dr. Schenerlen has been recognised as *privat docent* in Hygiene and Bacteriology.—*Vienna:* Dr. S. Fuchs has been recognised as *privat docent* in Physiology.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of the society was held on Oct. 30th, Dr. Mutch, President, being in the chair. The inaugural address for the session 1895-6 was delivered by Dr. G. V. Poore, Physician to University College Hospital, on "The Soil in its Relation to Disease and Sanitation." The origin, constitution, and properties of the soil were fully dealt with; some of the common disease germs present in the soil were alluded to, and also the power of the soil to assimilate dead organic matter, and render pathogenic bacteria harmless. Conditions of drought and moisture were considered in their relation to disease, and the evil consequences likely to result from allowing large tracts of land to go out of cultivation were commented on. A cordial vote of thanks to Dr. Poore was passed on the motion of Dr. Handford, seconded by Dr. Lamb.

AN UNFORTUNATE SCHEME.—The scheme of the Newport (Monmouthshire) Corporation to obtain a supply of water from Wentwood, about ten miles from the town, has been most unfortunate. The report of the two geological experts upon the site was presented to the committee last week. This recommends the abandonment of the scheme on the ground that, if the works were completed, in their opinion the reservoirs would not hold water. The experts exonerate the committee of the council, who had chosen the site, from all blame, as it would have been impossible to have said until the present stage had been reached that the geological formation was unsuitable. The amount of the contract was about £100,000, and the committee had been given power to borrow £250,000. The scheme has already cost £40,000. At present no further progress will be made with the works, although some other experiments may be carried out.

A NEW COTTAGE HOSPITAL AT FARNHAM.—The new Bishop of Winchester (Dr. Davidson) last week opened a cottage hospital erected under the bequest of the late Mr. George Trimmer and adequately endowed for the future. A site was given by the testator's two sons, Mr. R. G. Trimmer and Mr. C. E. Trimmer, Mr. J. A. Eggar presenting the designs. The hospital has a southern aspect, and the male and female wards (each containing three beds) open on to a long verandah, each ward being 21 ft. by 14 ft. There is an accident ward and a small operating room, the whole on the ground floor. Upstairs the only patients' room will be a day ward for convalescents. The cost of the building, exclusive of the furniture, was £2000. The honorary medical staff will include Mr. S. G. Sloman, jun., Mr. H. Sloman, Dr. C. E. Tanner, and Mr. J. Lorimer. There will be but one nurse, with a probationer and domestics.

WORKHOUSE ACCOMMODATION AT CARDIFF.—During the last few years the population of Cardiff has increased so rapidly that the present workhouse accommodation has been found insufficient. Last winter there was an excess of 100 male inmates over the proper number, and at present the workhouse is much overcrowded. The guardians then endeavoured to find some building which might be used for temporary accommodation, and also made applications to other unions to receive some of their inmates, but without any success. Two inspectors from the Local Government Board met a committee of the guardians last week, when it was stated that no further addition to the present number of inmates could be allowed. The committee have therefore decided to procure a site of about twenty acres, in the neighbourhood of Ely (Glam.), which will be suitable for new temporary, and eventually for permanent, buildings.

Digitized by Google

THE DIFFUSION OF SMALL-POX.—Last week, for the first time for sixteen weeks, there were no deaths registered from small-pox in the metropolis, although there was one in the suburban district of West Ham.

GUY'S HOSPITAL. — The treasurer of Guy's Hospital has received a cheque for £1000 from Mr. A. L. Cohen for the endowment of a bed in memory of his late son, H. A. Cohen.

THE NEW SOMERSET COUNTY ASYLUM.—At the last meeting of the Somerset County Council a contractor was appointed to build the Cotford Asylum, near Taunton, The cost of this new asylum, including furniture and fittings, will be £132,480. The contractor states that it is impossible to complete the building under two years, but it is thought that a portion may be completed and occupied before then.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The monthly meeting of this society was held at "Stanley's," Lavender-hill, S.W., on Nov. 13th, when a paper was read by Dr. Charles W. Chapman on Heart Disease in the Young. Stress was laid upon etiology, prognosis, and treatment, and an interesting discussion ensued, in which the President, Mr. T. S. Howell, Dr. A. D. Roe, Mr. A. E. Dodson, Mr. B. Duke, Mr. T. A. J. Howell, and others took part.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—A new wing of the Birmingham and Midland Eye Hospital was opened on Nov. 9th by Viscountess Newport. It contains a special department for the treatment of children, together with rooms for nurses and members of the staff. The out-patient rooms have also been enlarged, and a large ward for male patients has been constructed. The hospital was erected eleven years ago at a cost of £20,000, and a sum of £5000, has been expended in the recent alterations and additions. Last year there were 1100 in-patients and 24,000 out-patients.

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—The November meeting of this society was held on Saturday, Nov, 16th, at the Lewisham Infirmary, the President, Mr. J. R. Lunn, F.R.C.S., in the chair. Dr. Toogood, Medical Superintendent of Lewisham Infirmary, exhibited cases of Ununited Fracture of Femur cured by operation; Traumatic Gangrene of Foot; Multiple Perineal Fistulæ cured by External Urethrotomy; Symmetrical Paralyses caused by Lead Poisoning; Acute Conjunctivitis produced by Malingering; Pelvic Sarcoma; Exophthalmic Goitre; Malignant Myopia; Tubercular Synovitis following Acute Rheumatism; Malignant Tumour of Kidney; large Calcified Fibroma of Uterus. The President congratulated Dr. Beaumont, Dr. Quarry, and Mr. Spurrell on obtaining their appointments, and a vote of thanks to Dr. Toogood for his interesting series of cases concluded the proceedings.

LUNACY IN YORKSHIRE.—The best means of providing increased accommodation for lunatics in the West Riding was considered at a conference held on Nov. 11th in the Town Hall, Wakefield. Colonel Spencer Stanhope, C.B., chairman of the Asylums Committee, presided, and the company included representatives of nearly all the boards of guardians of the Riding and the chairman of the West Riding County Council. Colonel Stanhope said that the number of patients in the three asylums of Menston, Wadsley, and Wakefield in the year 1885 was 3858, and in 1894 it had risen to 4774, being an increase of 916 in ten years. The Asylums Committee were desirous of ascertaining whether suitable accommodation for harmless cases might not be provided in the workhouses, where the cost of maintenance was undoubtedly less than in the asylums. A separate asylum for the treatment of chronic cases would effect very little saving, as a special staff of officials would be required. After some discussion it was arranged that the subject should be considered by the individual boards of guardians, and the Conference adjourned.

BOOKS, ETC., RECEIVED.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Craig: Lunacy Law.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Diseases of Nails.

During the week marked copies of the following newspapers have been received:—*Macclesfield Courier, Manchester Evening News, Leicester Daily Post, Durham Chronicle, Birmingham Gazette, Gloucester Journal, Sussex Daily News, Eastern Daily Press, Sheffield Independent, Beverley Recorder, East Anglian Daily Times, Preston Herald, North Walsham Post, North Star, Belfast News Letter, Newcastle Chronicle, Western Morning News, Hastings Times, Family Churchman, Liverpool Mercury, Educational Review, Brighton Gazette, Man of Ross, Hotel, Brighton Examiner, Galignani Messenger, Doncaster Gazette, Oban Express, Oban Telegraph, Grimsby News, Truth, Hexham Herald, Ormskirk Advertiser, Berrow's Worcester Journal, Daily Argus, Lowestoft Standard, Medical Record (New York), Kent Messenger, Isle of Wight Express, Framlingham Weekly News, Manchester Guardian, &c., &c.*

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"IMPORTANT NOTICE."

TWO CORRESPONDENTS enclose to us copies of the following handbill—

Important Notice.—W. E. Hailstone, Cash Price Chemist, 152, Camberwell-road, S.E., begs to announce that he has arranged with Mr. Stafford Allen, R.D.S., Dental Surgeon, to attend daily at the above Address. Artificial Teeth at Moderate Prices. A Single Tooth from 2*s.* 6*d.*; A Complete Set from a Guinea. Repairs to Sets completed in two hours if required. Perfect Fit and Natural Appearance Guaranteed. Extractions: By Gas, from 6*s.* 6*d.*; Painless, from 2*s.* 6*d.*; Ordinary, from 1*s.* Stopping, from 2*s.* Scaling from 1*s.*

Dr. Morris Jenkins, M.R.C.S.Eng., L.R.C.P.Lond., attends daily. Hours of Consultation: Morning, 12 to 1; Evening, 8 to 9. Midwifery attended.

Note the Address—152, Camberwell-road, S.E.

Mr. Morris Jenkins must know that to have his name, address, and qualifications disseminated in this way is incorrect conduct.

Dr. Wm. Wallace.—Our correspondent should apply to any dealer in chemical apparatus. We believe that Messrs. Baird and Tatlock of 14, Cross-street, Hatton-garden, London, E.C., supply spirit lamps of the Bunsen or Argand type suitable for the purposes mentioned. Coal gas, again, may be had compressed in steel tubes. For incubation ordinary night lights are useful, placed at some distance beneath the incubator, the temperature being also regulated by the number used.

Cortex is recommended to write direct to one of the four Inns where he will get all particulars. The expense is chiefly the expense of living in London, and can therefore be made whatever a man pleases.

Mr. Arthur Franklin and *O. A. P.*—We never recommend individual practitioners.

Mr. S. S. Ashmore-Noakes's eulogy is one which we can endorse.

WILLIAM III. AND HIS PHYSICIANS IN 1700.

To the Editors of THE LANCET.

SIRS,—The following, taken from Law's "History of Hampton Court Palace," vol. iii., may interest your readers. In a letter dated June 11th, 1700, King William III. is reported to have had given him "a dose consisting of ale impregnated with the leaves of ground ivy, fir tops, hart's tongue, and wild carrot seed." At a consultation held between the physicians Sir Thos. Millington, Dr. Radcliffe, and Dr. Lawrence, "the first two doctors agreed in nothing, neither as to the disease nor as to the remedies. Dr. Radcliffe thought the swelling in the King's leg was little less than dropsy, and advised 'purging and asses' milk.' Millington, on the other hand, said both such remedies were contrary to the King's constitution, and he was for the King's taking garlic. 'That,' said Radcliffe, 'will destroy such weak lungs as the king's.' 'Weak lungs!' cried Millington in answer, 'why his lungs are the soundest part about him.'" On the night of Wednesday, June 26th, 1700, the King took a pill that the physicians gave him, composed of "pillula stomachicacum cum gummis, the volatile salt of hartsho n, and the syrup of violets." At the same time they prescribed "twenty drops of the tincture of the salt of tartar to be taken every day, and the juice of thirty hog-lice at 6 o'clock at night." It is surprising to learn that "the next day he looked very well

Digitized by Google

and was cheerful." But the success of a rival's remedy could carry no conviction to the minds of the other worthy medicos, and Lawrence, who sided with Millington, announced that he "had determined not to relinquish his own prescription of garlic." On June 27th John Locke, the philosopher, was sent for, and had an audience of the King. Whilst there he seems to have been asked as a scientific man to "take a diagnosis of the King's condition," and he was able so far to endorse Millington's opinion as to state that in his view, "if the King had a dropsy he would not have so fresh a colour." Thus fortified with the philosopher's pronouncement, Millington and Lawrence proceeded to treat his Majesty after their own fashion, and on the 23rd he was ordered "2 grains of scammony sulphurated, with 26 grains of the stomachic pills to be taken at night." In Vernon's account of an interview he had with the King a few days after he says: "I was at Hampton Court this morning, and the King seeming a little heavy I asked him if he were out of order; he said he should be very well if they would leave off giving him remedies, and that he had taken something that had put his stomach out of order." The writer says: "But the hour of his escape both from England and from the antagonistic remedies of his physicians had now arrived." Not yet, however, for we read further on: "Up to the last moment the doctors would not relax their hold on his Majesty. That same night a consultation was held and they prescribed a glyster." "I hope," says Vernon, "the King will be better when he is out of their hands at Loo." Next day, at six o'clock in the morning, he left for Margate, on his way to Holland. The night of his return to Hampton Court he was given "half a dram of the cream of tartar twice a day; a ptisane (?) to be taken at pleasure, of the clarified decoction of barley, after a warm infusion of eryngo roots condited, sal prunellæ, and the spirit of black cherries." "The frequent use of tablets made of the species de Althæa, with sal prunella, loaf sugar, and mucilage of tragacanth." A few days after the treatment was changed to "Nynsichtius' elixir vitrioli and spa water." These were followed in quick succession during the next month by "gentian, centaury, tartar vitriolated, salt of wormwood, salt of steel, balsamic syrup, Epsom salts in chicken broth, crabs' eyes, steel prepared with sulphur, hogs' lice, chalybeate pills, elder flowers, after which recourse was again had to the old prescriptions." Was it to be wondered at that the King at last succumbed?

I am, Sirs, yours truly,

East Molesey, Oct. 17th, 1895. W. W. HARDWICKE, M.D. St. And.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Can you give me the titles of any books, monographs, or other papers dealing with the subject of surgical interference in cases of pulmonary cavities, together with the names and addresses of the publishers? Yours faithfully,

Nov. 18th, 1895. H. G. A.

*** THE LANCET, vol. ii., 1880, contains an account of a debate at the Royal Medical and Chirurgical Society upon this subject. Monographs on the operative treatment of pulmonary cavities will also be found in many issues of THE LANCET, the references to which will be found in Dr. Neale's excellent "Digest." Dr. R. Douglas Powell's book, "Diseases of the Lungs" (H. K. Lewis, 136, Gower-street, W.C., third edition, 18s.), also gives much information.—ED. L.

THE *Secretary of the Vegetarian Society* has yet to learn that editors are not responsible for the opinions of their correspondents.

Parish Council is requested to restate his query more fully, giving names and places.

Mr. W. F. Dale is thanked for his communication.

"THE BRITISH MEDICAL BENEVOLENT FUND."

To the Editors of THE LANCET.

SIRS,—May I ask you to be kind enough to allow me to add the following names to the list of contributions to the British Medical Benevolent Fund?

Dr. Ryding Morse	...	£0 10	6	Dr. Ogier Wood	... ...	£0 10	6
Dr. Connel	... ...	1 0	0	Dr. Finlayson	... ...	10 0	0
Mr. Satchell	... ...	2 2	0	Dr. Luff	... ...	1 1	0
Dr. Duffin	... ...	5 5	0	Sir James Paget	... ...	10 10	0
Mr. Butlin	... ...	2 0	0	Surgeon-Major Gardner		5 5	0
Mr. C. A. Aikin	... ...	2 12	6	C. G. E.	... ...	0 10	6

I am, Sirs, yours faithfully,

Brook-street, W., Nov. 20th, 1895. W. H. BROADBENT.

MEASLES IN DOGS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers give any information as to whether dogs (or other animals) have been known to suffer from measles? I have been attending some twenty odd cases of measles, one of my patients being in my hospital in which I live. I know my dog (fox terrier bitch) has been into this particular child's room. For the past few days the dog has evidently been very unwell, refusing her food, &c. Yesterday I noticed a rash on her abdomen identical with the eruption of measles in appearance. If this is true measles, are there any other instances known? I am, Sirs, yours truly.

Nov. 18th, 1895. M. H.

A STORY.

THE following anecdote has a somewhat *trovato* flavour, but the original narrator vouches for its authenticity:—

At a certain military station a newly-fledged assistant-surgeon who inhabited one of the "pill-boxes," as the quarters assigned to the medical staff were profanely designated, found himself unable to sleep one night in consequence of the persistent coughing of an unfortunate soldier who was doing sentry-go hard by. Perhaps philanthropy may have been the motor; but, at any rate, the wakeful surgeon left his warm couch, and proceeding to the adjoining dispensary compounded a powerful, if somewhat nauseous, draught, which he confidently believed would overcome the most inveterate cough that was ever pumped from bronchitic lungs. Armed with this potent weapon, and wrapping himself up carefully—for it was very cold—the would-be philanthropist made his way to the sentry-box, and ordered its astonished occupant to take the medicine forthwith. The man objected; but the officer was peremptory, and at length, amidst much spluttering and objurgation, the physic was swallowed. Needless to say, it acted like a charm (physic always does under similar circumstances), and from that moment until the rising sun once more awoke the multifarious noises of the camp not a sound disturbed the solemn stillness. Next day at the breakfast-table, while dilating on the marvellous qualities of his cough-no-more specific to an admiring circle of subalterns, who one and all advised him to have it patented, the complacent young gentleman, to his great surprise, received a summons to the orderly room.

"What is the meaning of this, Mr. Blank?" said the colonel, with an expression wherein sternness and amusement strove for mastery. "Here is Private Rooney, who says you forced him to drink some stuff last night which he believes was poison, for he has felt very ill ever since."

"I simply cured his cough for him, sir," replied the assistant-surgeon proudly, "and he ought to be grateful, instead of trying to trump up such a preposterous charge."

"Tell the officer what you complain of," said the colonel, addressing the late sentry.

The *patient malgré lui* had a brogue you might cut with a knife, as the saying is. "I beg your pardon, sorr," he exclaimed in response to the C.O.'s request; "shure it's the truth, and nothing but the truth, I'm afther tellin' you. The doctor he comes out all wrapped up in a blanket, wid a glass in his fist, and he says, says he, 'Dhrink this, me man; it'll do ye good.' 'Is it whiskey, sorr?' said I, for I had me doubts. 'Whiskey, ye drhunken spalpeen ye,' says he—savin' your presence, sorr—'no, it ain't whiskey, it's good medicine, that's what it is, an' ye'd better be afther tossing it down the red lane widout makin' any more fuss.' 'Not me, sorr,' says I; 'shure, if it's medicine yez'll be wantin' it for the poor min in hospital.' But it warn't no use. 'Av ye doesn't take it this instant minute,' says the doctor in a thunderin' rage, 'I'll clap you in the guard room.' And so I had to swallow the bastely stuff."

"Well, the beastly stuff cured your cough, at all events," said Mr. Blank, when decorum once more resumed its wonted sway. "You had been barking away for an hour or more, and I did not hear you cough once afterwards."

"Faix, then, it warn't me ye heard barkin' at all," cried Private Rooney triumphantly. "It wor Bill Smith, whose place I hadn't tuck more'n two minutes whin you come wid the poison."

Secretary.—The General Medical Council do not, it is understood, object to unqualified assistants being employed by practitioners when resident in or near their employers' houses, but the Council will not allow unqualified persons to conduct branch practices or dispensaries which are situated at a distance from the principal's house and are not under his immediate supervision. A notice to this effect appears in our advertisement columns weekly.

MEDICAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—A few weeks ago, having a small practice to dispose of, I wrote particulars to a local agent. A person presented himself, and examined my books and became acquainted with the nature of my practice. He left, promising to see me again. I next hear of his prowling about the village, canvassing my patients for a club, and next that he has taken rooms and on his own account commenced practice. Such conduct amongst gentlemen needs no comment—it is too low, and disgusts one. But I think it a serious matter for agents, and I have no doubt a strong one would find some legal remedy for such conduct. It may be warning, however, to others; and I should advise practitioners to be very careful, and not regard so much their testimonials as to require information with respect to their personal character.

I remain, Sirs, yours truly,

Nov. 18th, 1895. PRACTITIONER.

*** It is not the first time that this mean and disgraceful trick has been brought to our notice. In every case where a vendor has been treated in this way he should write a full account of the occurrence to the agent.—ED. L.

ERRATUM.—We regret that by an unfortunate error "gramme" was printed for "grain" in all the figures of the pulse-tracings illustrating Professor Bradbury's Bradshaw Lecture in our last issue.

Pharmaceutical Products of High Repute.

SACCHARIN "TABLOIDS."

In cases of Diabetes Mellitus, Glycosuria, Gout, Obesity, and diseases in which sugar is contra-indicated, dietetic regimen is almost always looked upon as more or less of a penance, and patients are sure to be thankful if their food can be made more palatable and varied by means of a harmless condiment. Diabetic patients, from the very fact that sugar is denied them, often have such a craving for sweet things that the withholding of them exercises great influence on their mental condition. This shows the enormous benefit which the introduction of saccharin in a soluble form has conferred upon all those whose bodily conditions make it necessary that sugar in every form should be avoided. It is not too much to say that monotonous and unpalatable diets do more harm to many patients than the diseases from which they suffer.

The absolute harmlessness of Saccharin has been conclusively proved by numerous and thorough scientific experiments and researches, and experience has corroborated the results arrived at. It has been shown that Saccharin produces no injurious effects whatever upon the body; that it is discharged, unchanged and in its entirety, through the urine and fæces; that it is absolutely inoperative as a retarding agent on bodily functions; for instance, it exercises no influence on either assimilation or digestion. When, therefore, sugar (the ordinary carbohydrate) in any form is prohibited as an article of food or as a condiment, it may be asserted, without fear of contradiction, that Saccharin, while satisfying the palate of the patient, cannot possibly aggravate the existing malady; on the contrary, its antiseptic influence may be for good.

Saccharin is invaluable as a sweetening agent for unpalatable medicines where sugar is contra-indicated, or where it is desired to make the volume of medicine as small as possible. In the form of soluble Saccharin powder it is sent out in little oval bottles with a tiny spoon attached to the stopper, each spoonful holding an equivalent in sweetening potency to one lump of loaf sugar. The many varieties of gluten food, such as gluten bread, biscuits, &c., may be conveniently and pleasantly flavoured by means of this preparation. One or two of these little spoonfuls added by the patient to a dose of medicine containing such nauseous drugs and chemicals as Cascara, Sulphates of Magnesium and Sodium, Bromides of Potassium, Sodium, or Ammonium, or persistent bitters like Nux Vomica and Strychnine, will effectually mask the objectionable taste. Perhaps a more palatable and convenient form of Saccharin is the "Tabloid" prepared by compressing this chemical. "Tabloids" are of the greatest convenience to those travelling or away from home during the day, as each tiny "Tabloid" is equivalent to a lump of sugar and may be substituted for that flavouring agent for sweetening tea, coffee, &c.

Soluble Saccharin Powder is supplied to the medical profession in ¼-oz. and 1-oz. bottles with scoop, at 1/2 and 3/10 per bottle. Saccharin "Tabloids," containing ½ grain in each, are supplied in bottles of 100 and 200 at -/7 and 1/1 each.

MENTHOL SNUFF (B., W. & CO.).

This preparation has become deservedly celebrated for its marked local anæsthetic, vascular, stimulant, and antiseptic properties. It has been approved by the highest medical authorities for its sedative action on the nerve terminations, and for its property of causing prompt contraction of the relaxed nasal vessels. It is composed of menthol, cocaine, ammonium chloride, camphor, and lycopodium. It has been suggested to us that the issue of a smaller size would increase the sphere of its usefulness, and we have accordingly decided to issue a small size in addition to our older 1/- size.

Supplied to the Medical Profession in attractive tin boxes at -/5 and -/8 per box.

TEREBENE.

Terebene has been found of the most decided utility in the treatment of many bronchial troubles. Pure Terebene possesses the same stimulating expectorant properties as a large group of terebinthinates; it is, moreover, much more suitable for inhalation purposes than the latter, as all the resinous material has been eliminated in the process of manufacture. The drug tends to liquefy the sputum and facilitate expectoration; these qualities are enhanced by its inherent antiseptic properties when employed as an inhalant in the treatment of chronic pulmonary affections, as it exerts its antiseptic influence at the seat of infection. Terebene is more generally employed as an inhalant. If the vapour is to be inhaled dry, the Terebene may be used with a B., W. & Co. "Pinol-Eucalyptia" Dry Inhaler or a Menthol Pocket Inhaler.

Terebene supplied to the Medical Profession, in 1-oz., 2-oz., 8-oz., and 16-oz. bottles, at -/9, 1/-, 2/-, and 3/9 each.

"EMOL-KELEET."

Since our earlier notices to the medical profession regarding this preparation we have received many encouraging reports of the beneficial effects of its use in Surgery and Dermatology. It has not only been prescribed for its absorbent, antipruritic, and emollient qualities, but also as a diluent for such antiseptic agents as Loretin, Dermatol, Iodoform, Boric Acid, Chrysophanic Acid, Hydro-Naphthol, &c. Owing to the fact that it is a natural powder containing a large proportion of native silicates, "Emol-Keleet" is chemically stable, and is therefore freely prescribed as a diluent for potent medicinal agents without fear of combination taking place. In addition to these chemical advantages, its soft, silky texture, soothing influence, and other physical qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other drying and dusting powders have failed.

THE LANCET, in an appreciative notice of this preparation, says:—"On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

BRAITHWAITE'S RETROSPECT OF MEDICINE eulogises it as:—"The most beautiful, impalpable mineral powder with which we are acquainted, and promises to supersede all the older forms of dusting powder."

NEW ASEPTIC VACCINATOR.

(REGISTERED No. 263010.)

Suggested by J. IREDALE, L.R.C.P., L.R.C.S.

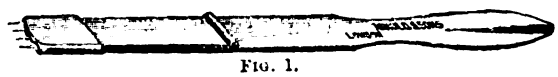

FIG. 1.

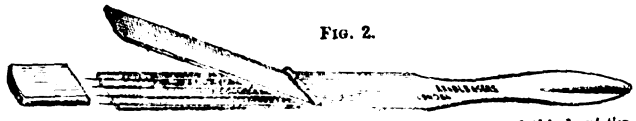

FIG. 2.

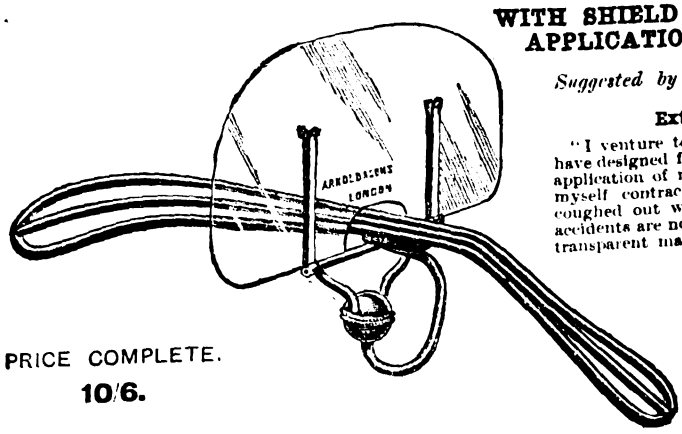
PRICE COMPLETE, 6/6.



Extract from the BRIT. MED. JOURNAL, Sept 21st, 1895:—

"Mr. J. Iredale, Mablethorpe, sends us a description of a new Vaccinator which has been made for him by Messrs. Arnold & Sons. Fig. 1 shows the instrument closed, ready for use. Fig. 2 shows the part with grooves and needles *in situ* raised from a hinge joint; the other end is a blunt lancet with a shallow groove for the reception of lymph. As needles can be had in every house, the advantage of this vaccinator will be easily seen, this being a great improvement on the old type of vaccinator of this description, when the needles are permanently fixed and the great difficulty is keeping the points

NEW TONGUE DEPRESSOR.

(REGISTERED)

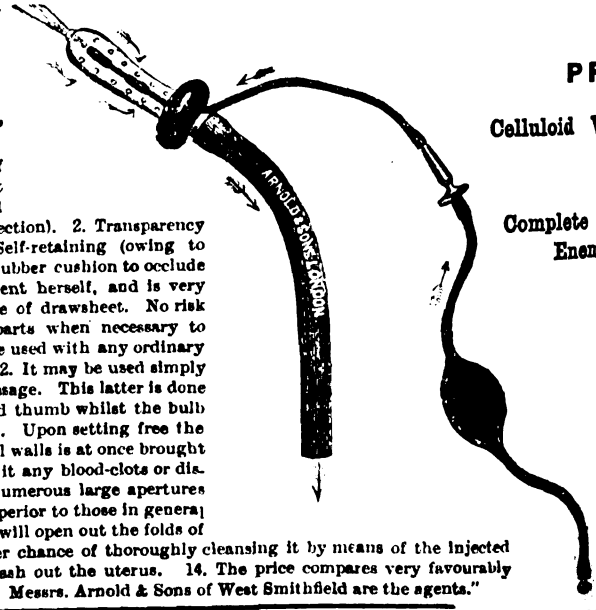
WITH SHIELD FOR PROTECTING THE FACE DURING APPLICATIONS TO THE THROAT IN DIPHTHERIA.

PRICE COMPLETE.

10/6.

Suggested by ALEX. W. W. DOWDING, M.D., M.S.

Extract from THE LANCET, August 3rd, 1895:—



"I venture to bring to the notice of the profession an [illegible] have designed for the protection of the face during the application of remedies to, the throat in cases of diphtheria. I myself contracted diphtheria on two occasions from a patient coughed out whilst examining in the usual way, and as such accidents are not uncommon, it occurred to me to introduce a transparent material, and I found that mica or talc answered exceedingly well, and I am now able to [illegible] tion to make a careful examination in comfort. The tongue depressor is well curved and has a [illegible] the face shield is of mica, the carrier being [illegible] ball and socket joint, and sliding backwards [illegible] a bar or under surface of the depressor, and [illegible] is freely movable and can be used for [illegible] By removing the carrier the depressor can be [illegible] ordinary way. Being of mica the shield is [illegible] parent, and easily kept clean. To prevent [illegible] cold weather it may be warmed before use. [illegible] ficial illumination throughout the shield is [illegible] candle, lamp, or Mackenzie's laryngoscopic mirror. Messrs. Arnold & Sons of West Smithfield are the makers."

NEW CELLULOID VAGINAL DOUCHE.

(PATENTED.)

Suggested by R. H. RAINS, M.R.C.S.

(Vide BRITISH MEDICAL JOURNAL, July 6th, 1895.)

PRICE:

Celluloid Vaginal Douche, **7/6.**

Complete with Seamless Enema, **10/6.**

Extract from THE LANCET, May 25th, 1895:—

"The following relates to a special form of vaginal douche for which certain important advantages are claimed—viz.: 1. Shape and curve of pipe facilitate introduction (oval on section). 2. Transparency ensures cleanliness. 3. Unbreakable. 4. Self-retaining (owing to expanded extremity). 5. Inflated adjustable rubber cushion to occlude the vulval outlet. 6. Can be used by patient herself, and is very comfortable in use. 7. It entirely obviates use of drawsheet. No risk of wetting bed. 8. Readily takes into four parts when necessary to clean. 9. Cannot get out of order. 10. May be used with any ordinary india-rubber syringe. 11. Large waste pipe. 12. It may be used simply to irrigate the vagina or to flush out that passage. This latter is done by clamping the waste-pipe with the finger and thumb whilst the bulb of the syringe is compressed two or three times. Upon setting free the waste-pipe the muscular action of the vaginal walls is at once brought into use to expel the injected fluid (and with it any blood-clots or discharge) from the vaginal cavity through the numerous large apertures in the tube. If only used as a syringe it is superior to those in general use, as the comparatively large celluloid pipe will open out the folds of mucous membrane, and thus give a much better chance of thoroughly cleansing it by means of the injected fluid. 13. With special tube may be used to wash out the uterus. 14. The price compares very favourably with any other apparatus for the like purpose. Messrs. Arnold & Sons of West Smithfield are the agents."

ON

URINARY CALCULI: THEIR FORMATION AND STRUCTURE.

Delivered at the Summer School of Medicine for Qualified Practitioners in Cambridge, in June, 1895,

BY SIR GEORGE MURRAY HUMPHRY, M.D. CANTAB., F.R.S., &c.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF CAMBRIDGE.

GENTLEMEN,—Having commenced my medical career as an apprentice at Norwich and as a pupil at the Norwich Hospital, my thoughts were early directed to the subject of urinary calculus, particularly in its practical bearings; and for many years subsequently I had much experience in the treatment of stone in Addenbrooke's Hospital. It is not, however, my intention to take you at any length over the well-trodden ground of the treatment of this malady, but rather to discuss for a short time the structure and mode of formation, or building up, of stones in the bladder and some of the forms they assume, matters which, I think, have some interest and some difficulties, and which have not received much attention. I do not mean the microscopical constitution or the chemical composition, but rather the more obvious physical structure, of calculi. For this purpose I have gone, more or less carefully, over nearly all the collections in London as well as that in Norwich and that in our own museum here. I do not wish by this to raise your expectations of what I have to say, for I must confess to being not very proud of my results in ascertaining the causes of the peculiarities which some calculi exhibit, and I am reluctantly obliged to leave many of these points to the more fertile reflections of yourselves and others.

Let me first draw your attention to a few remarkable specimens. I show you here one of the largest calculi which has been found in the human bladder, and which presents some points of historic and collegiate, as well as of clinical, interest. According to an account of it by Dr. Heberden given in the Philosophical Transactions[1] it weighed thirty-three ounces and three drachms, and was taken after death from the wife of a locksmith at Bury St. Edmunds. It was shown to Charles II. at one of his visits to Newmarket, "when at least half an ounce was broken off before the king to show him that it was formed in the manner animal stones usually are." It was of an "oval shape, flattened on one side and its surface smooth." The specific gravity was 1·75. It was presented to Trinity College, Cambridge, by Mr. Samuel Battely, Member of Parliament for Bury St. Edmunds, about the middle of the reign of Queen Anne, and was preserved in the library of that College, together with other calculi, a human skeleton, and a curious assortment of animal and other specimens, indicating that the studies at the College were not limited to books and stars, philosophy and casuistry, but were to be extended, practically, to the various regions of science. Reminders of this, and also of the fact that libraries were the only museums of that time, are still given by a human skeleton in the library at Queen's College and by one in the library at Jesus College. About thirty years ago the calculus and its companion specimens were transferred to the pathological museum of the university. It is of clinical interest forasmuch as we learn that "the woman had felt much less pain than might have been expected from so large a stone, and might probably have lived much longer with it had she not thought herself well enough to attempt a journey on horseback; for while she was riding she was suddenly seized with violent pains that obliged her to be taken off the horse immediately. After this she could never make water unless the stone was first moved, and she continued in great agonies till her death." This corresponds with the fact that the stone is of very compact structure, composed chiefly of concentric layers of uric acid with some oxalate of lime and a thin coating of fusible calculus. It measures 15 in. by 13½ in.[2] It formed, no doubt, very slowly during many years (we cannot tell how many, for estimates as to the rate of growth of calculi are little more than guesses) in the bladder which gradually became accustomed to it and did not resent its presence or object to its weight. Hence the comparatively little suffering and the long duration of life. In the Norwich collection there is a six-ounce phosphatic calculus which was less meekly tolerated by the female bladder, for it is said to have been ejected spontaneously through the urethra. A still larger stone, weighing forty-four ounces, taken after death from the bladder of Sir Walter Ogilvie, is in the museum of the Royal College of Surgeons of England. He had paraplegia, and the stone is phosphatic. A calculus in St. Thomas's Hospital museum weighing twenty-five ounces was, at about the same date as the large one I have shown you, taken after death from Sir Thomas Adams, the philanthropist, draper, Lord Mayor of London, president of St. Thomas's Hospital, and the intimate friend of Charles II., to whom he contributed large sums of money, and who created him a baronet, and for his loyalty to whom he was imprisoned in the Tower. He was educated at Cambridge and founded the Professorship of Arabic in this University in 1632. The calculus resembles the one I have shown you, being composed of compact and regularly laminated uric acid formed around an oval nucleus of more porous uric acid. It appears to have caused little pain or inflammation of the bladder or disturbance of the general health, and, finally, to have proved fatal in consequence of a fall which the worthy baronet had, at the age of eighty-one, in descending from his carriage. It presents a groove dividing it into two unequal parts. This groove, which was probably caused by the projecting hinder edge of the trigone of the bladder, is deep and with defined edges on what we may suppose to have been the under part of the stone, and becomes shallower and gradually disappears towards the upper part. In a sermon preached "at the solemnity of his [Sir Thomas Adams's] funeral" on March 10th, 1667, the groove is described as being, "as it were, a paved way, or rather a channel cut through the stone, for his water to pass," otherwise "the stoppage of it must of necessity have very much added to his smart and lessened his days." The stone is rather uneven and slightly rough on the exterior, being covered, as these large calculi not infrequently are, with a layer of more porous uric acid or urate of ammonia. This coating extends over the groove as well as over the rest of the calculus. A drawing of the calculus, with other particulars respecting it and Sir Thomas Adams, is given in Vol. XXI. of the Transactions of the Pathological Society by Mr. Charles Williams of Norwich, to whom I am indebted for a loan of the sermon.

The largest stone which has, I believe, been removed entire and successfully by the lateral operation is in the Norwich collection. It weighs fifteen ounces and was extracted by Mr. Harmer, a Norfolk surgeon, in the presence and with the aid of Gooch, who gives a representation of it in his work on Surgery. A urinary fistula remained, which Gooch says was kept clean by a little dog licking the part, which gave the patient more ease than any application his surgeon furnished him, and as long as he lived (five years) the dog was his surgeon and kept the wound tolerably clean and easy. The next largest, so far as I know, removed successfully and entire by the lateral operation is in the museum at St. George's Hospital. It weighs eleven ounces, is composed in its middle of uric acid and some oxalate of lime, with a thick coating of compact, concentrically marked phosphate of lime. It was extracted from a man aged forty-three, with much difficulty, by Mr. Warrington Haward, in St. George's Hospital, who found it necessary to extend the incision into the rectum. A fistula remained, in this case as in the preceding one, but the man was alive and, with that exception, well some years afterwards. In the museum at Guy's Hospital is one weighing thirteen ounces extracted successfully by Mr. Mayo of Winchester, but it broke and was removed in fragments. One in the same museum weighing nine ounces was successfully removed by Sir A. Cooper, and another weighing sixteen ounces was also removed entire by the same surgeon, but the patient sank. In the museum of the Royal College of Surgeons of England there is a still larger calculus, the largest, I imagine, which has been removed by the lateral

[1] Philosophical Transactions, 1752, vol. xlvi.

Digitized by Google

operation. It was dragged through the perineum by Cheselden and weighed seventeen ounces, but the patient sank the next day. One weighing thirteen ounces failed to be extracted by Mr. Dalrymple of Norwich. The largest which I have seen extracted is the uric acid calculus I show you, weighing eight ounces, which I removed, by means of a strong scoop, through the perineum of a man in the neighbourhood of Newmarket. He recovered without a bad symptom.

On looking over the Norwich collection one is struck with the number of large calculi which have been removed successfully by the lateral operation and which bear testimony to the reputation as lithotomists which the surgeons of that city have long held. Most of them are sound, hard, uric-acid stones, and, so far, tell of the sound constitution of the patients, contrasting with these nine calculi from India, sent us by a former pupil, which, though containing uric acid and oxalate nuclei, are, for the most part, composed of phosphates. There is a phosphatic calculus from a negro in the museum of King's College Hospital, and a calculus weighing three ounces and a half, apparently phosphatic, with curious projecting knobs, in the museum of St. George's Hospital. It was removed by the lateral operation from a man who had spent the greater part of his life in India. He did not recover. In the museum at St. Mary's Hospital there is a phosphatic calculus from India, with two concentrically marked, apparently uric acid nuclei as large as filberts joined by a band like the Siamese twins. There are, however, in the museum of St. George's Hospital two oxalate of lime calculi from India, and in the Royal College of Surgeons of England there is a collection of many calculi, removed by operation from Hindoos and Afghans, which are composed apparently of uric acid; they are compact and present the usual concentric rings. Thus we see that the inhabitants of that region of the world, who are mostly vegetable-eaters, are liable to the same varieties of calculus as our own countrymen. The oxalate of lime is said by Castor to be a more frequent nucleus than uric acid in India, and is attributed by him to the vegetable character of the diet.[3] This fine bristling specimen of oxalate of lime weighing four ounces—a good example of the calculus spinosus of Celsus—was successfully removed by myself from a middle-aged man. The largest example of this variety of calculus which I have seen weighed eight ounces. It is in the Royal College of Surgeons of England and was removed from a man in Norfolk aged sixty, who appears to have gone on well for six weeks, but then to have become depressed and sank. These results of the lateral operation pale, however, in interest since the revival, under antiseptic advantages, of the supra-pubic method, by which great stones have recently been removed with success and without much difficulty. In the Royal College of Surgeons of England there is a calculus weighing thirty-four ounces and a half, six inches long and four inches in diameter, which was removed at Cairo by Mr. Milton, by the supra-pubic operation, from an Egyptian fellah, aged sixty, who was at the time in bad health. The operation is described as one of "laparotomy," for the peritoneum, as well as the bladder, was opened above the pubes. The man lived two months and a half and then died from kidney disease.[4] In Ashhurst's "International Cyclopædia of Surgery," vol. vi., p. 162, a case is quoted in which a stone weighing forty ounces and a half, and measuring seventeen inches in circumference, was removed from a man aged thirty-nine, by the supra-pubic method, by a Brussels surgeon, the patient dying eight days afterwards. This is probably the largest stone ever removed from the living human bladder. It is somewhat strange, and not particularly creditable to me, that, having tested this method in 1848 on a lad aged fourteen who had shown symptoms from birth,[5] I should not again have resorted to it till within the last few years, when it had been revived by others, especially as the case taught me that I over-estimated the ill-effects that were likely to result from extravasation of urine into the loose tissue about the bladder. I carefully emptied that viscus before the operation, instead of washing it out, and perhaps filling it with antiseptic fluid, as is now done. Yet, in spite of my precautions, when I cut into the bladder, to my dismay a considerable quantity of urine (pent up, I suppose, in the ureters, as may be seen to have occurred in a specimen in the Middlesex Hospital, where, with a calculus in the bladder, the ureters, pelves, and calices of the kidneys are enormously dilated) flowed out and soaked into the surrounding tissues; yet no ill resulted. The thickened bladder had misled me somewhat as to the size of the stone which, as you see, is not very large, and weighed only 750 grains. The lad made a good recovery; and some time afterwards I extracted by the lateral method a stone which had formed upon and was adherent to the cicatrix of the former operation.

The nucleus.—The nucleus, which is the incipient or foundation, and usually the central, part, is obviously the most important part of a calculus, that to which attention has been most especially directed. It commonly forms in the kidney and consists of uric acid, oxalate of lime, or cystine—of the first most frequently, of the last rarely. Its formation depends upon one or both of two causes: first, an unusual quantity of one of the more easily precipitable constituents of the urine (uric acid or oxalate of lime), when a very slight cause will lead to the precipitation and union of the crystals, which may take place in the uriniferous tubes or in the calices of the kidney; secondly, a slight increase, or alteration in the quality, of the mucus in the secreting tubes or calices of the kidney may exert what is known as a colloidal influence upon the forming crystals, modifying their shape or reducing the crystallisable material to a more or less amorphous and cohesive condition, in consequence of which they adhere together into masses or calculi. This alteration in the mucus may possibly, in some cases at least, be caused by the abnormal presence of crystals in the kidney, the two conditions thus acting and reacting on each other and combining in the production of calculus. That the mucous condition is a very important feature in the process is shown by the well-known experiments of Mr. Rainey, followed by the observations of Dr. Ord;[6] and it is maintained that without this colloidal influence the crystals have very little tendency to adhere together. Streaks of the granular or amorphous uric acid and of dumb-bells of calcium oxalate formed under this influence are not uncommonly found in the uriniferous tubes, especially in infants and young children, constituting the "uric acid infarction" of Virchow. Many years ago a medical man about sixty, of gouty diathesis and sensitive temperament, who was liable to attacks of pain in a kidney, told me that after each attack he was conscious of something passing along the ureter into the bladder, and, being apprehensive of the formation of calculus, he used to watch on each occasion for the passage with the urine of what he called a "bleb of mucus." His apprehensions were realised, for after one of these attacks the looked-for "bleb" did not appear, a stone formed, and I subsequently lithotrised him. He recovered from this, but died subsequently from some kidney disease. When two or more calculi find their way into the bladder they usually, I believe, come from the same kidney; and in the Transactions of the Pathological Society[7] two instances are recorded by Dr. Harley, in each of which numerous small calculi were found in one kidney (in one case in the left kidney, where they were of triple phosphate, and in the other instance in the right kidney, where they were of uric acid), the opposite kidney being quite free. Here the formation of the calculi evidently depended upon some peculiarity, probably in the mucous secretion, of the kidney. The importance of this view of the pathology of calculus with regard to the investigation of the causes of the disease in particular districts and to the measures to be taken for its prevention must be borne in mind. It gives some support to the principle involved in Dr. Yellowby's idea that the Norfolk dumplings and the indigestion resulting from them were *a* cause, if not *the* cause, of the prevalence of calculus in that county. The porous character of the nucleus, as compared with the layers formed upon it, which may often be observed, accords with its mucous origin. Two or more nuclei are not very infrequently found in a calculus. These are usually of uric acid or urate of ammonia. In this specimen (Fig. 1) there are four nuclei; and in one in University College five uric acid nuclei are embedded in a mass of phosphates, forming one large stone. In some instances they are small, and in

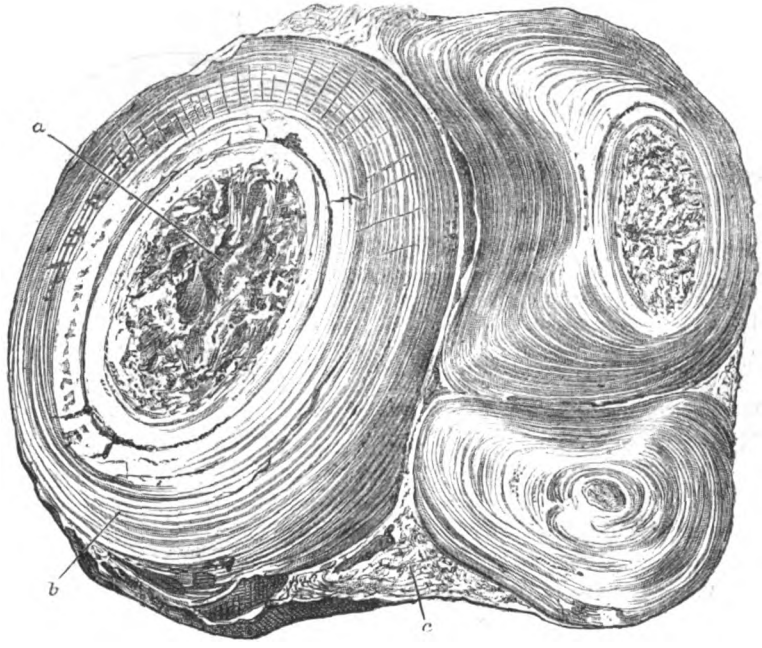
me flattened by apposition. The junction of such may ve taken place in the kidney, though I am not aware that nal calculi have been found with multiple nuclei. Now and en one sees two nuclei united by a band (as just mentioned) e Siamese twins and enclosed in a common envelope—

FIG. 1.



Four nuclei in one calculus. (Cambridge collection.)

deed, a large number of small calculi may be united by osphates into a single stone, as in a specimen examined y Dr. Beale.[8] Occasionally larger stones are thus joined ogether, the uniting medium being commonly phosphatic, nd two or more calculi, lying in apposition in the bladder, may ecome covered over and cemented by phosphatic material. n one specimen two good-sized, cone-shaped calculi, with eir bases apposed but not in contact, are enveloped in a ass of porous, apparently phosphatic, material. In a specimen in King's College Hospital a small porous uric acid stone is appended to, and united by phosphates with, a large, compact, uric acid stone which has an oxalate nucleus. The most remarkable example of such union is presented by the large seventeen-ounce calculus removed by Cheselden and represented in Fig. 2, taken from the catalogue of the Royal College of Surgeons of England (Plate III., Fig. 1). In it three large uric acid calculi, but little adapted to one another and not very closely approximated, are united by earthy phosphates. The central part of each of the three consists of porous uric acid or urate of ammonia, and the surrounding concentrically marked and more compact uric acid looks as if the calculi had lain in apposition, and that some shifting of them upon one another had taken place before they became united by the phosphatic deposit. The multiple nuclei are, as I have said, commonly composed of uric acid or urates. The oxalate calculi are usually single, and rarely have more than one nucleus; and, indeed, this material is seldom passed in the form of gravel. There is, however, in the museum in Guy's Hospital a specimen in which four nodulated nuclei of oxalate of lime, as large as beans, are united by urates and surrounded by layers of uric acid, forming a large stone; and in the museum of the London Hospital there is a large calculus composed of two calcium oxalate calculi of unequal size enclosed in a mass of phosphates. When nuclei remain separate they form multiple calculi which, by apposition and mutual friction, commonly become faceted, and often in a manner rather difficult to account for. This, however, is not always the case. In the museum in Guy's Hospital there are sixteen calculi taken from a bladder after death; they are nearly as large as walnuts and are spherical and smooth on the surface. Here, also, are sixteen spherical, smooth calculi of rather smaller size. In the Norwich collection there is a large cuboidal calculus with four facets, upon each of which is applied a flattened calculus faceted on one side, the whole forming a nearly spherical mass which resisted the attempts to remove it by the lateral operation. The portions came away separately subsequently, through the wound, into the bed, but the patient did not recover.

When the nucleus or the calculus has reached the bladder it does not comport itself quite like an ordinary foreign body. The latter, as we know, whether it be a piece of bougie, a hairpin (as in this specimen), a mass of soap (as in two specimens in the Royal College of Surgeons of England), or any other substance, becomes encrusted with phosphates consequent on the irritation caused by it in the bladder, the only exception to this that I have known being the specimen in the Royal College of Surgeons of England in which a needle is the nucleus of a uric acid stone, whereas a calculus usually increases by the addition of material like that of which it is composed. The reason of this difference must be that the calculus causes less irritation than a foreign body, which perhaps we should scarcely have expected. That a hairpin should be a source of considerable worry may easily be believed, but we should not have thought that a piece of bougie would have proved a greater irritant than a spinous oxalate calculus. True, the calculi may, and often do, become coated with phosphates. Usually, however, the addition to a calculus of uric acid, oxalate of lime, or cystine does not consist of phosphates, but of uric acid, oxalate of lime, or cystine, as the case may be. It is somewhat remarkable that this should be so, and should sometimes go on steadily for many years, as in the instance of the woman whose large

FIG. 2.

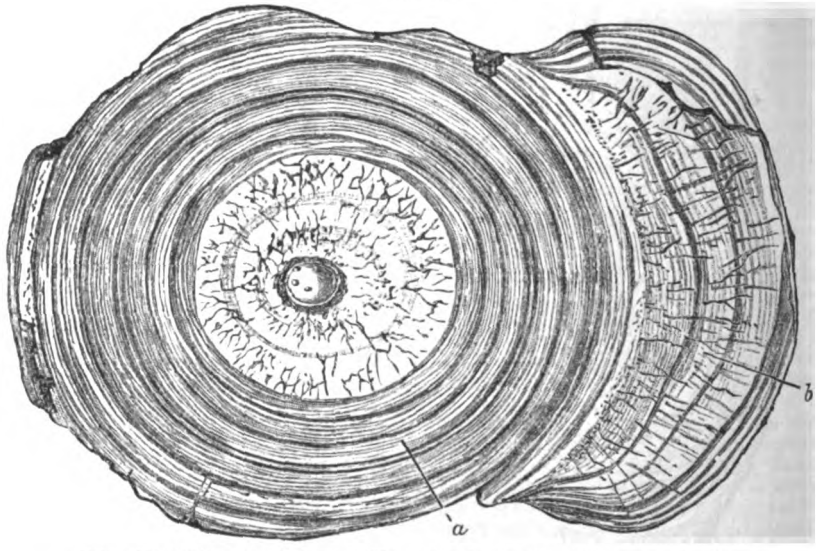
[8] Urinary Deposits, 1869, p. 419.



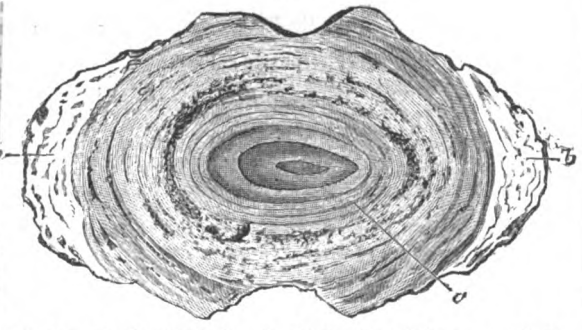
Digitized by Google

stone I have shown you, in that of Sir Thomas Adams and in others, especially when we remember that oxalate of lime or oxalic acid and cystine are not commonly present in the urine at all, or indeed in the blood,[9] and that uric acid is present in small quantities, about six to ten grains only being passed in the four and twenty hours, and it does not exist in a free state in the urine, but is held in solution by an alkaline base from which it must be liberated before it can settle on a calculus.

Increase of calculi in size.—The addition to a calculus is probably effected by the same means as that by which the nucleus is formed—that is to say, by the influence of the mucus in the urine. This, where in contact with the stone and resting in the interstices of its surface, attracts, sets free, and modifies the uric acid, increasing its cohesive quality and causing it to settle upon the stone, and the quality of the uric acid thus added will depend upon the amount and quality of the mucus. When the latter is in small quantity the acid crystals will be little altered and will be slowly deposited, constituting the compact material of which the greater number of large, slowly forming calculi are composed. When the mucus is more abundant the uric acid is deposited in greater quantity, more quickly, and in more granular amorphous form and more irregularly, constituting the porous variety of which many stones are entirely, or in varying degrees, composed. The porous and the compact materials often vary in different periods of the formation of the same calculus, not infrequently succeeding one another and telling of successive periods of greater or less irritation of the bladder. The same remarks apply probably to the oxalate and cystine calculi, though variations in density in different parts of these are not so common as in those composed of uric acid.

Form of calculus.—Each variety of calculus takes its own form, the uric acid being oval and flattened (which is also commonly the case with the cystine), and the calcium oxalate being spherical. This cannot depend upon the surroundings, for the form differs in the two cases and each assumes its particular form from the first—that is, when the stone is small. In the calcium oxalate the form may be given by the crystals radiating from the centre in needle-like lines and shooting out into the spines or tubercles on the surface; and in the uric acid calculus it must likewise be some disposing property in its particles which gives the flattened oval shape and which also causes the tubercles often seen on the surface and the lamination in its structure. Though the predominant form of the uric acid calculi is a flattened oval, especially when the substance is compact, it is liable to great varieties. Often it is prolonged in certain directions by the deposit upon it of the porous uric acid or urate of ammonia, or of the two combined, the particles of which, being more or less deprived of their crystallising quality, lose proportionately their form-determining property. It not uncommonly happens that the calculi are prolonged at one or both ends of the oval; and in Sir Henry Thompson's cabinet in the Royal College of Surgeons of England there is the curious instance of a square-shaped calculus in which the four angles have been prolonged by porous uric deposit upon each, the whole being covered over by more compact uric acid, as though, for a given and short period, the irritation of the bladder by the four corners had determined the presence of mucus upon them, with the consequent porous condition of the uric acid. Occasionally, as in the specimen represented in Fig. 3 from the catalogue of the Royal College of Surgeons of England, a uric acid calculus is capped at one end with a thick layer of compact striated uric acid. The smooth groove on the surface between the two parts in this stone has suggested that the one part may have been formed in a cyst and the other part in the bladder, but, in addition to the fact that encysted calculi are usually phosphatic, there is a specimen in the College in which there is a similar cap at each end. A calculus in the museum at St. Mary's Hospital has a small cap of the like material at one end, and the whole is covered with a layer of phosphate. A specimen in Sir Henry Thompson's cabinet looks as if a number of small uric acid calculi had settled upon and adhered to an elongated stone of the same material, this being, I suppose, in reality, an exaggeration of the granular or tuberated condition not uncommon in uric acid calculi. The nucleus may be at one end, the calculus having been prolonged in the opposite direction into a finger-like form by compact or porous uric deposit, as in this specimen. Here is a triangular flattened calculus; and in a specimen in the museum at St. George's Hospital a calculus has acquired an hour-glass shape from increase at both ends, the nucleus being in the middle. This, I should say, is thought to have been due to the solution of the middle part by the urine, which can scarcely have been the case, for the calculus presents the same smoothness and character of contour over its whole surface. Such constrictions or grooves dividing a calculus into two or more equal or unequal parts are occasionally seen (Fig. 4) and they are commonly attributable to projections, into the bladder, of the hinder edge of the trigone or some other bands which have impressed the calculus. They are generally smooth, as smooth as, or smoother than, other parts of the surface of the calculi. Occasionally, but more rarely, the constriction has been caused by the formation of one part of the stone in a cyst and of the other part in the bladder, and represents the narrow orifice of communication between the bladder and the cyst. In such cases, as I have said, the

FIG. 3.



Uric acid calculus capped at one end by compact uric acid. (Catalogue of the Royal College of Surgeons.)

[9] Dr. Beale found cystine continuously present for a long time in the urine of a young man who was otherwise healthy.—Urinary Deposits, 1869, p. 384.

Digitized by Google

calculi are, so far as I have seen, phosphatic.[10] Various forms are given by the addition of lime salts, and it is to be remarked that these are often deposited upon the ends of the oval uric acid calculi, extending their long axes and leaving the rest of their surfaces uncovered, of which Fig. 4 is an

FIG. 4.

Calculus with phosphatic deposit at both ends and deep groove in the middle. (Cambridge collection.)

illustration. Does this indicate that the salts have a tendency to settle upon the ends or more prominent parts of the calculi, as in the instance of the square uric acid calculus before mentioned, in which a collection of porous uric acid is seen in each of the four corners? This large calculus, the other half of which is in St. Bartholomew's Hospital, is partially covered by thick, defined, irregular bands of phosphates, the intervening parts of the surface being free. The cause of this irregularity in the deposit I cannot tell. The calcium oxalate calculus is less liable to varieties of form than the uric acid, perhaps because the needle-like radiation of its crystals is a more determined factor, and leads to the more definitely spherical shape. In Guy's Hospital, however, there is a square calculus of this material, also a cast (I believe) of one which is elongated, one of large size marked by a deep groove, and others of different shapes. In the museum of St. Thomas's Hospital there is an example of several faceted calcium oxalate calculi quite smooth on the surface and nearly colourless, both these peculiarities being very rare, for this variety of calculus is usually single and dark-coloured. In that museum also is an instance in which knobs of oxalate have formed upon a uric acid calculus.

Concentric and radial fissuring and fragmentation of calculi.—There is in the uric acid calculi, evinced more particularly when they have become dry, a tendency to crack into layers and also to split radially, such as may be seen in the transverse section of the branch of a tree. This probably depends upon the concentric and radially fibrillar arrangement of the particles of the calculus, resembling that which was noticed by Mr. Rainey in the small calcium carbonate spheres resulting from the action of gum upon ammonium carbonate. It facilitates probably the breaking up of the stone under the lithotrite and may possibly, under certain conditions, such as some change in the cementing material of the calculus, lead to the spontaneous division of the stone into fragments in the bladder. A supposed example of this is represented in Plate XII., Fig. 10, of the catalogue of the Royal College of Surgeons of England, taken from a specimen in the museum at St. Bartholomew's Hospital, in which a portion of the outer layer of a calculus has become detached. One cannot but suspect that such a fragment may have been broken off in sounding. There do not appear to be any other fissures in the calculus, and it is difficult to see how it can have been spontaneously detached in the bladder. The same remarks apply to the two cases mentioned by Mr. Southam;[11] and in the third case, communicated to him by Mr. Luke, the lithotrite had been used and the stone had twice slipped from under it. Instances of supposed spontaneous disintegration of calculi are also given by Dr. Ord.[12] Mr. Coulson[13] mentions a case in which fragments of the shell of a medium-sized uric acid calculus were spontaneously detached and passed from the bladder. The detachment was judged to have been caused by the violent contact of two stones during severe attacks of bladder irritation.[14]

Colour and concentric colour markings.—Each variety of calculus acquires its particular colour. The uric acid attracts the urochrome of the urine, which gives it, whether in the form of gravel or stone, a reddish-brown or fawn colour. Owen Rees is said to have seen one perfectly white.[15] The dark colour of the calcium oxalate has been attributed to an admixture of the colouring matter of the blood; but its uniform diffusion seems rather to point to its depending upon some modification of the colouring matter of the urine which takes place during the formation of its crystals. I have already mentioned an instance in which the colour was absent. The oxalate so rarely passes as gravel that we have not much opportunity of determining its colour under those circumstances. The disposition of the colour in alternating deeper and fainter lines shading into one another, and giving the concentric markings common in compact uric acid calculi, is not quite easy to account for. The lines are usually in complete circles, though varying in depth and definiteness in different parts of the circumference and in different parts of the thickness of a calculus: Yet in this thirty-two-ounce stone they have evidently been formed in fairly regular order through many years. Such colour-markings are by no means peculiar to uric acid calculi. They are sometimes seen faintly in the oxalates and in the harder phosphates; though in the latter they may have relation to admixture with uric acid or calcium oxalate in certain of their layers. They may be discernible in gall-stones, and are often strongly marked, as in this specimen, in the stones composed mainly of carbonate of lime, found in the intestines of horses, and also in other instances. Are we to suppose, in the case of uric acid calculi, that they depend upon alternating changes in the urine which indicate subtle changes in the system not otherwise evinced, such as might be caused by changes of food, changes of temperature as in the rings in trees, or other influences? They are not numerous enough to be diurnal and they are too numerous to be annual. Or do they depend, like the concentric rings in bone, which exhibit, and are caused by, the arrangement of the bone corpuscles, upon some determining quality in the material itself? The frequently occurring calculi in which layers of compact and porous uric acid exist in super-imposed layers with varying amounts of urate of ammonia, also the "alternating calculi" composed of uric acid, calcium oxalate, and phosphate of lime occurring and recurring in varying layers, must depend upon corresponding changes in the urine and form an argument in favour of the former hypothesis. At any rate, a question of some interest in pathology and physiology is opened up by these markings and other alternations observable in calculi.

I have mentioned that the more porous uric acid substance differs from the compact in the greater contingent of mucus, which gives to it a more or less granular or amorphous character, and that it does not acquire the regular colour markings just described. It does, however, often present a radially coarse fibrous structure with traces of concentric layers. In this specimen (Figs. 5 and 6) the radiating bars are crossed and connected by tiers of concentric strata; and the two have the effect of dividing up the calculus in such a manner as to enclose regular squares or elongated spaces or small chambers with defined walls and angles. How the curious arrangement came about I cannot tell. The porous calculi usually conform to the flattened oval uric acid type, and when the porous is added to the compact uric acid it commonly does the same; but, as I have before said, it may be limited to some part or parts of the surface, perhaps to the more projecting parts, as the ends, and give in that case an elongated form to the calculus.

Erosion of calculi in the bladder.—I have not been able to

[10] There has been lately added to the museum at Cambridge the bladder, with cystitis and thickened wall, from a lad who died in Addenbrooke's Hospital. The ureters were dilated, and there was hydronephrosis on both sides. On the left side of the bladder, near the entrance of the ureter, but separate from it, are two small orifices of sacculi, each of which was filled by a phosphatic calculus nearly the size of a walnut, of hard structure and with concentric laminæ. These two sacculi displaced and stretched the ureter, and must in some degree have obstructed the passage of urine through it. On the right side, also near the ureter, but not interfering with it, is a small sacculus which did not contain a calculus. There was no calculus in the bladder, and it is not easy to decide what determined the formation of the sacculi and the formation of the calculi in the two sacculi on the left side.

satisfy myself of any clear evidence of the solution or erosion of calculi in the bladder. The grooves on the surface often attributed to that cause are usually smooth and crescentic or circular, and are obviously due to the projection of rugæ or bands from the internal surface of the bladder, which have interfered with the deposit upon the stone where they embraced it. The calculus is not uncommonly thus modified,

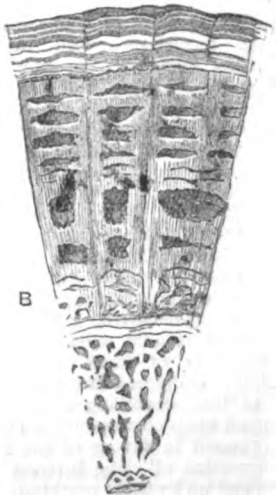

FIG. 5.

Porous uric acid calculus, showing radial and concentric disposition of fibres. (Cambridge collection.)

acquiring an hour-glass shape or being constricted in various ways. The hinder edge of the trigone, as seen in Sir Thomas Adams's stone, may be the cause, or the pressure of the urethral orifice upon a calculus which projects into the more yielding prostatic part of the urethra. These supposed evidences of erosion are most common in compact uric acid calculi, which one would not judge most likely to undergo solution. The coloured rings may now and then be seen to be incurved at the grooves, but they more commonly stop

FIG. 6.

Section of above, magnified, showing more or less rectangular chambers enclosed by the radial and concentric fibres.

short and terminate in rounded ends at the margins of the grooves (as seen in Fig. 4); or they may terminate even more abruptly so as to give some countenance to the erosion theory, not, however, enough to counterbalance the facts that the grooves are smooth; and in some instances, even where the rings terminate, as I have mentioned, the grooves are known to have been caused by constricting bands, and the remainder of the surface of the calculus gives no indications of a solvent action. Further, in some a coating of deposit, uric or phosphatic, has formed over the whole surface, including the grooves, which scarcely accords with the view of erosion of any part. The rough, sharply defined depressions or holes seen upon some calculi are more suggestive of erosion, but they probably depend upon irregularity in the phosphatic or other deposit rather than upon erosion. There is in the museum at St. Thomas's Hospital a large uric acid calculus resembling that from Sir Thomas Adams, and with a similar constriction or groove. The exterior is described as being "water-worn and the colour washed out." It presents to me more the appearance of being coated with a layer of rather lighter material than the rest of the stone, intermixed probably with some phosphates, which had been deposited in an irregular or tuberculated manner, so as to give the impression that the surface had been acted on by the urine or "water-worn." One is rather at a loss to know by what ingredients in the urine the solution whether of uric or phosphatic calculi, could be effected. It is possible that certain changes in the urine, acting upon the cementing material of the surface of the calculus, as suggested by Dr. Ord[16] with reference to the disruption of calculi, might lead to the removal of particles which pass away with the urine; but the whole subject is, I think, still *sub judice*.

Phosphatic calculi.—Phosphatic calculi do not assume any regular or special form, like the uric or oxalate calculi. When added on to other calculi the phosphatic concretion commonly continues the form of that upon which it is laid, or, as I have already said, it may prolong it in certain directions or be deposited in various ways; and it is said not to possess the property of cohering into a calculus upon a calculus, except in the presence and under the colloidal influence of mucus or pus. In the museum of St. Mary's Hospital there is a uric acid calculus with phosphatic deposit on one side only, as though the stone had rested quietly on one surface in the bladder and the phosphate had been limited to the uncovered or exposed part. In the museum is also a curious pyriform phosphatic calculus composed apparently of eight faceted pieces accurately adapted to one another; and a finger-like process which extended into the urethra is marked off from the remainder by a deep constricting groove formed by the neck of the bladder. It was taken after death from a man who had for many years suffered from the effects of fracture of the spine. In the same museum there are also two disc-shaped faceted phosphatic calculi of the size of beans, removed from the phimosed prepuce of an old man who died from hydronephrosis. They are said to have caused retention of urine. It is often stated that phosphatic deposit, being due to inflammation of the bladder and consequent decomposition of the urine, is a final deposit upon a calculus and is not followed by any other material. This, however, is disproved by numerous specimens in which rings of uric acid and calcium oxalate are seen encircling the phosphatic formation or alternating with it. In such examples the alternating and waving disposition of the oxalate presents a variegated and pretty section, not unlike, as was remarked to me, for a lady's brooch. In the museum example at the Royal College of Surgeons of England a phosphatic calculus with a considerable projection at one part is encircled by a waving line of calcium oxalate. In these cases the phosphate is usually compact, indicating that the bladder inflammation upon which it depended was not very severe. I do not think that the looser, softer phosphatic substance, the result of more active inflammation, is followed by other deposit—at least, I have not met with an instance in which it was so.

Bone, teeth, and hair in the bladder.—These portions of bone with teeth and hair, covered with phosphate of lime, were removed through the urethra from the bladder of a woman who quite recovered from the operation. The finger introduced into the bladder did not discover any other stone. The supposition is that the masses originated in the ovary, probably in a congenital cyst, and found their way into the bladder, after the manner in which an extra-uterine fœtus or the bones of one—occasionally travels into the rectum. In University College there is a phosphatic calculus elongated at one end where there is a fœtal tibia which formed the nucleus of the stone. After the death of the patient other remains of a fœtus were found in the right iliac fossa. Dr. Beale mentions an instance in which hairs that had escaped from an ovarian cyst into the bladder formed the nuclei of calculi, and gall-stones are said to have been passed from the urinary bladder, having found their way into that viscus in consequence of a communication found between it and the gall-bladder.[18]

ON SOME OF THE IMMEDIATE RESULTS PRODUCED BY CASTRATION IN CASES OF ENLARGEMENT OF THE PROSTATE.

BY C. W. MANSELL MOULLIN, M.D. OXON., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL; EXAMINER IN SURGERY IN THE UNIVERSITY OF OXFORD.

A GREAT deal of evidence has been collected in the last year or two upon the question of the influence exerted by the testes upon the growth and nutrition of the prostate. Orchotomy for enlargement of the prostate has now been performed more than a hundred times, and it may be regarded as proved that it is practically always followed by atrophy of the gland. The wasting does not, it is true, set in with equal rapidity in all cases alike; in one it is said to have been upwards of a year before there was distinct diminution in size; and the extent to which it is carried varies, depending probably upon structural differences, for, while it is well established that both glandular overgrowth and stroma undergo fatty degeneration and disappear, it is not so clear what effect is produced upon true myomata (as distinguished from the common form of localised nodular overgrowth) or upon a gland in which the tissues have already undergone fibroid transformation. But almost without exception, whenever a definite result has been recorded, there has been a more or less conspicuous reduction in size. So far as the enlarged gland is concerned the evidence is mainly clinical, it is true; but there are three instances in which it has been confirmed by post-mortem examination. One, eighteen days after operation, has been recorded by Griffiths;[1] a second, eleven days later, by myself;[2] and the third by Professor White of Philadelphia,[3] in which the patient died on the evening of the second day. In the first of these three cases fatty degeneration followed by disintegration and ultimate disappearance of all the cell elements, epithelial, connective tissue, and muscular alike, was described. In the second, the microscopic examination of which was made for me by Mr. A. B. Roxburgh, the surgical registrar of the London Hospital, although there was distinct reduction in size (as shown by the wrinkled state of the mucous membrane), and especially in consistence, no histological change could be made out. The epithelial cells preserved their columnar shape and normal appearance, and there was no evidence of proliferation. In the third the report states that "the stroma of the gland shows beginning proliferation of the connective tissue cells, but especially of the muscle cells. The acini tubules are also becoming filled with proliferated columnar cells, and here and there some fine granular matter may be seen in the tubules; some of the cells appear to contain fine granules, which have not taken the stain, evidently fat. The changes are typical of beginning atrophy." It is true that there is here a certain amount of discrepancy, the results of the microscopic examination in my case not confirming what was found in the others, although in respect of duration it stands almost midway between them. But no great weight can be attached to this, as it is well known that in the case of the normal prostate, in animals as well as in men, several instances are on record in which atrophic changes have been delayed for a singularly long time after the performance of orchotomy. The point, however, to which I wish to draw attention is not so much the ultimate result as the strange and unexpected effect upon micturition that has frequently been noted as occurring within a few hours of the operation, an effect so unexpected that in many of the cases it has been neglected altogether as an unaccountable accident and in others has been received with polite but unmistakable scepticism. Recovery of voluntary power over the bladder is recorded in many instances as having occurred as early as the fifth or sixth day—in several, within a few hours. Sometimes it has been permanent; more frequently, and especially in those instances in which it has been regained within a few hours, it has been lost again for a time, and then, at the end of a week or so, gradually and finally been restored. Several of these cases have been under my own observation, and I think the circumstances under which they have occurred throw a certain amount of light upon the causation. In one case orchotomy was performed for prostatic retention. Undoubtedly this had been immediately occasioned by congestion and œdema; but before the operation was performed the patient was kept in bed for a fortnight under the usual treatment suitable to such cases, so that the congestion might have time to subside. During that fortnight there was but little change for the better; the day after the operation it was distinct and marked. More progress had been made in twenty-four hours than in the preceding fortnight. In a second, in which the most prominent symptom was a most intractable cystitis, the patient himself noticed a decided improvement in the size and the strength of the stream on the same evening. In a third case in which I was consulted no urine had been passed, except by catheter, for a considerable time. Two hours after the operation urine was passed naturally, and this continued for five days. Then retention occurred again, and a catheter was required at frequent intervals for about three weeks, when voluntary power began to return once more and this time continued. This case I regard as especially significant; for Mr. A. Hunt of Wolverhampton, under whose care it was throughout, wrote to me that for some time after the operation the muscles around the anus were exceedingly irritable, so that the finger, when introduced for the purpose of examining the condition of the gland, was tightly gripped, whereas previously the orifice had always been patulous and the patient had suffered from the ordinary difficulty of retaining the motions so common in cases of prostatic enlargement. Similar experiences have been noted by other surgeons. In a case recorded by Gavin,[4] in which there was absolute retention, the catheter having to be introduced every four hours day and night, voluntary micturition took place eight hours after the operation, the first time for three weeks. The next day the catheter was needed again; the third day it was passed for the last time, micturition henceforth being entirely voluntary. In another case, under the care of Lilienthal,[5] there was no improvement after six weeks' palliative treatment. Twenty-four hours after the operation there was slight, but distinct, remission of symptoms. The third day all the improvement was lost, and then, on the fifth, it began again and this time continued steadily. And Watson[6] records another case of almost complete retention, the patient being only able to void spontaneously an ounce or two of urine in the twenty-four hours, drop by drop, in which all treatment, including the use of the catheter, was stopped immediately after the operation. Palliative measures had been tried without improvement for five days. Orchotomy was performed. In the first twenty-four hours, although the bladder filled considerably, it did not become over-distended, and the patient voided at each urination more than he had done previously; and at the end of thirty-six hours the pain and desire to urinate ceased, so that he could sleep for two hours without being disturbed.

Various explanations have been suggested for the rapidity with which this improvement sets in. Clearly, even when recovery of the power of voluntary micturition is delayed for so long as a week, it cannot be accounted for by any organic change. In spite of the fact that in Professor White's case there was evidence of cell proliferation, such as precedes atrophy, by the evening of the second day, it must be admitted that no fatty degeneration or absorption can be so speedy as to produce a tangible effect upon the diameter of the prostatic urethra within the space of eight, and still less of two, hours. For this reason I cannot accept the explanation that has been offered by Professor White.[7] He suggests that the rapidity may be accounted for by changes taking place in a valvular median lobe. Very little alteration in such a structure might produce a noticeable amelioration of obstructive symptoms; but, slight as these changes need be, there is no time for them, and, even if the immediate improvement could be accounted for on this theory, it entirely fails to explain the relapse which, as I have shown, so frequently follows within the first few days. Organic changes, such as cell proliferation and the like, are quite out of the question; the only possible explanation for such rapid alternations is to be found in the condition of the circulation through the part. I do not, however, in

the least agree with those who attribute the improvement to the disappearance of congestion and œdema under the influence of rest and palliative treatment. As I have shown in the above cases, rest and palliative measures had been tried in many of them, if not in all, for days and even for weeks before the operation, without producing the least effect. The reduction in size of the enlargement cannot be explained by this. No doubt it is due immediately to the diminished amount of blood circulating through the gland, but this diminution is brought about, not by the cessation of congestion, but by the active spasmodic contraction of the walls of the vessels. The exciting stimulus is not the removal of the testes, but the sudden ligature of the spermatic plexus of nerves in the cord. This is a factor in the operation the importance of which has apparently not attracted attention. The circulation through the prostate, there is no doubt, is under the control of a part of the nervous system that is directly connected with the testes through the spermatic plexus. Ligature of these nerves causes reflex constriction of the vessels in the prostate, and a corresponding diminution in size. Then, later, as the effect passes off, the walls of the vessels relax again, the congestion returns, and all the symptoms come back for a while, to disappear finally when the atrophic changes have advanced sufficiently to produce a permanent reduction in size. Such reflex muscular spasm after operations of this kind is no exceptional phenomenon. As can be well understood, it is not equally manifest in all cases alike; the conditions preceding the operation are in all probability somewhat stringent. Sometimes it affects the walls of the bloodvessels entirely or mainly; sometimes it involves other muscles as well. In Mr. Hunt's case, for example, the sphincter ani was conspicuously affected; and in one recorded by Hayden[a] not only this muscle but the compressor urethræ was involved, and there was such severe spasm for twenty-four hours after the operation that a catheter could not be passed and the bladder had to be aspirated. Fortunately the muscular spasm is rarely so severe or so widely spread as this, but it seems that not infrequently it is sufficiently general to produce a material effect upon the swelling of the mucous membrane that lines the prostatic urethra. Whether this explanation is correct or not—and it seems to me to fit in with the ascertained facts, and with all of them, much better than any other that has been suggested—the occasional occurrence of immediate improvement after orchotomy, usually of a temporary character, with or without spasmodic contraction of the sphincter ani or of the compressor urethræ, or of both together, is not a matter that can be questioned.

Wimpole-street, W.

A CASE OF PERFORATED GASTRIC ULCER; OPERATION; DEATH ON THE SECOND DAY FROM PERFORATION OF A SECOND ULCER.

BY E. W. SELBY, M.B., B.S.LOND., F.R.C.S.ENG.,
SURGEON TO THE DONCASTER INFIRMARY.

A DOMESTIC servant aged seventeen, was suddenly seized, at 3.50 P.M. on Nov. 6th, 1895, while working in the kitchen, with severe pain in the abdomen. She screamed out with the severity of the pain, sank down on to the floor writhing in agony, and vomited. The bowels had acted naturally in the morning, and the last food taken before the attack was dinner at 1 P.M., a meal ordinary in quality, but meagre in amount from lack of appetite. A medical man, who happened to be passing the house at the time, was called in, and found the girl collapsed, with cold extremities and rapid, feeble pulse. She said the pain started in the left hypochondrium, spread quickly over the whole abdomen, shot through to the back, up the back of the neck, and down both legs to the feet. He put the patient to bed and ordered her to have nothing by the mouth but milk and soda-water by teaspoonfuls. Hot bottles were put to the feet, and brandy and a quarter of a grain of morphia administered hypodermically. He saw the patient again at 9 P.M. She had then rallied from the state of shock, was flushed, had a full pulse of 110 to the minute and a temperature of 100° F. She had vomited once only since the initial emesis, the vomit consisting of a little curdled milk. There was slight distension of the abdomen and acute tenderness over the whole of it. As the pain was still very severe half a grain of morphia was injected under the skin. I saw the patient forthe first time at 10.30 A.M. on the following morning, Nov. 7th. She was extremely anæmic. She lay on her back in bed with both knees drawn up, and complained of pain all over, but especially in the abdomen and in the back of the neck. Her temperature in the mouth was 102·6°, and the pulse 120, full and bounding. There was slight general distension of the abdomen, which was acutely tender all over. The tongue was clean, moist, and very pale. The respiration was purely thoracic—45 to the minute. There was resonance over the whole abdomen and also over the situation of the liver, the liver dulness being altogether absent. There were hæmic murmurs in the chest, and a loud venous hum in the neck. The pain had kept her awake all the night. She had vomited a little more curdled milk. The urine had been passed naturally, and a natural motion had been voided in the early morning. The act of defecation caused great increase in the pain, and the ingestion of even a teaspoonful of water had invariably been followed by a sharp stab of pain in the left hypochondrium, so severe that the patient preferred to bear the intense thirst that resulted rather than take anything into the stomach. The patient had not complained of any symptoms of illness before the present attack, but on questioning a history of increasing pallor, with headache, lassitude, shortness of breath, palpitation, and swelling of the feet and legs, extending over a period of twelve months previous to the present trouble was obtained, with amenorrhœa of five months' duration. For three years she had suffered more or less constantly from pain in the epigastrium and middle of the back after meals, followed occasionally, although rarely, by vomiting, which afforded relief to the pain. These symptoms had been much worse during the six months previous to the present illness, but the patient had concealed her symptoms in order to avoid losing her situations. There had never been any hæmatemesis. The bowels had been costive, but had acted daily or every other day. The appetite had been very poor for the last six months. With this history the diagnosis of perforated gastric ulcer was almost certain, and although many valuable hours had been lost, and peritonitis was well established, operation was urged as giving some, albeit a very slender chance of recovery. The patient was carefully moved into the Doncaster Infirmary, but owing to a delay in obtaining the consent of the relatives, who lived at a little distance, the operation could not be undertaken till 3.30 P.M. on Nov. 7th, nearly twenty-four hours after the occurrence of perforation.

Operation.—Under A.C.E. mixture an incision was made at the outer edge of the left rectus, commencing half an inch below the costal margin, vertically downwards along the edge of the muscle for four inches, the lower end reaching a little below the level of the umbilicus. Hæmorrhage having been arrested and the peritoneum carefully opened throughout the whole length of the wound, on retraction parts of the stomach, tranverse colon, and small intestine were exposed, with patches of lymph covering them. No perforation was seen in the part of the stomach-wall exposed, but on manipulation curdled milk escaped, and on passing the finger up beneath the ribs a smooth round hole could be felt high up on the anterior surface of the stomach near the small curvature, a little below and to the left of the position of the cardia. As it was impossible to reach the perforation through the wound made the incision was prolonged upwards and inwards obliquely across the upper part of the rectus muscle, close to the margin of the thorax, to the left side of the ensiform cartilage, the superior epigastric artery being divided on the posterior aspect of the rectus, after that muscle had been cut through. The length of this second incision was about five inches and a half. Both hands could now be introduced, and the upper part of the front wall of the stomach drawn up near the surface. The left lobe of the liver was exposed and seen to be covered with patches of lymph. The perforation in the stomach was a smooth round hole, of such a size as just to admit a pea, and the peritoneal coat around it was much thickened for a radius of an inch by firmly adherent lymph. The wall of the stomach around the perforation was excised in elliptical fashion, at a distance of from one-eighth to a quarter of an inch from its margin, and the opening thus made was closed by a row of eight Lembert sutures,

[a] New York Medical Record, May 18th, 1895.

Digitized by Google

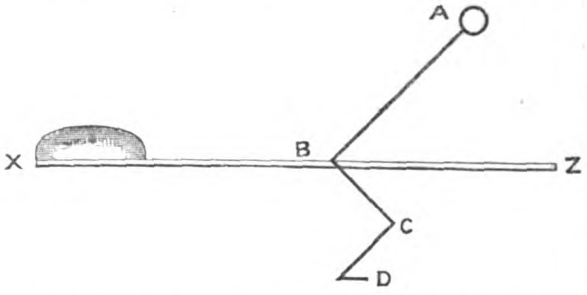
two at each end extending beyond the aperture. Fine silk was used for the sutures, and after the closure of the first row four additional stitches were inserted to secure tight closure of the opening. Just after the sutures were tied the patient retched, and no leakage occurred. The whole peritoneal cavity was then thoroughly flushed with several gallons of hot boiled water, the lymph being peeled off the peritoneal surface of the intestine as far as possible, particular attention being paid to the left hypochondriac region and the flanks. The lower end of the wound was prolonged for about an inch to enable the flushing to be done more thoroughly. When the abdominal cavity appeared clean it was carefully dried with lint sponges, and the wound was then sewn up without drainage. The operation lasted an hour and a half, and was followed by very little shock and no sickness. A hypodermic injection of a quarter of a grain of morphia was given after recovery from the anæsthetic. The pulse immediately after the operation was 144 and of good strength. The after-treatment consisted in the administration of enemata of two ounces of liquid peptonoids with a tablespoonful of solid beef peptones in suspension every four hours, half an ounce of brandy being added to the first three injections. Nothing was given by the mouth except hot water, a teaspoonful at a time, in just sufficient quantity to moderate the intense thirst. At 11 P.M. the temperature had fallen to 100·6°, the pulse remaining at 144 and of fair strength. There was slight distension of the abdomen below the bandages, but the pain was much diminished and the patient expressed herself as feeling much better. One-sixth of a grain of morphia was injected, and the patient slept well all night. On Nov. 8th the temperature was 101° and the pulse 144 and good. The patient said there was no pain, only a feeling of soreness about the wound. The bowels had acted early in the morning painlessly, and the abdominal distension had subsided. At 11 P.M. the temperature was 100°, the pulse maintaining its rate and other characters. The bowels had acted again naturally and without pain. There had been no nausea since the operation and the nutrient enemata were well retained. The patient said she felt she was getting better, and asked for something to eat. The hot water relieved the thirst. She slept well through the night. On Nov. 9th, at 8 A.M., the patient complained of more pain, quickly fell into a state of collapse, and died at 9.30 A.M.

Necropsy.—A post-mortem examination was made twenty-seven hours after death. The stomach, liver, and intestines were adherent to each other and to the wall of the abdomen beneath the wound by recent lymph. There was a small collection of turbid fluid in front of the stomach. The rest of the peritoneal cavity was dry. The line of suture in the anterior wall of the stomach could be seen, but the stitches were embedded in lymph. On removing the stomach a second perforation, a smooth, round hole nearly as large as a threepenny piece, was found on its posterior wall, exactly opposite the first on the anterior wall, near the upper border, and nearer to the cardia than to the pylorus. The peritoneal coat of the stomach around the second perforation was quite smooth and glossy, destitute of lymph, but intensely injected over an area of about an inch in radius from the margin of the opening. The peritoneum forming the small bag showed no sign of inflammation. The seat of suture was tested by pinching together the posterior perforation with the fingers, after ligature of the pylorus, and then filling the stomach with water under pressure through the cardiac orifice; it was found to be quite watertight. On opening the stomach the ulcer on the posterior wall was seen to extend in the mucous membrane from one-sixteenth to an eighth of an inch beyond the margin of the perforation. It was thus sharply conical and obliquely so, the internal ulceration extending an eighth of an inch beyond the peritoneal perforation on one side and only one-sixteenth of an inch on the other. There were no other ulcers in the stomach.

Remarks.—The following appear to be the principal points of interest in connexion with the case. 1. The question as to the advisability of operating after peritonitis was established. The severity of the symptoms in this case was not such as is usually met with in cases where a gastric ulcer has perforated when the stomach is full of food. The comparatively good condition of the patient, and the fact that the symptoms of perforation set in nearly three hours after the last meal taken, at a time when it might be hoped the stomach was empty, encouraged me to operate, even in the presence of acute general peritonitis. That the stomach was empty at the time of perforation was shown at the operation, the material extravasated consisting only of curdled milk (taken after the onset of the symptoms) mixed with the gastric secretion. 2. The position of the incision. I selected the lateral in place of the median incision, under the impression that better access to the whole of the anterior surface of the stomach would be obtained through a wound situated over the middle of that organ than by means of one over its pyloric end, the localisation by the patient of the stabs of pain produced by the ingestion of liquids in the left hypochondriac region assisting me in the decision, although the localising value of such pain as indicating the situation of the perforation is perhaps doubtful. The upper part of the rectus muscle had to be cut across in prolonging the incision; but if a median incision had been made originally, a free transverse cut close below the costal margin would have been necessary to obtain free access to the part of the stomach wall implicated, which would have weakened the abdominal wall more. The whole of the stomach was easily accessible through the wound made. 3. The satisfactory progress of the case after operation. The pain was greatly relieved, the tenderness and distension of the abdomen disappeared, the temperature fell from 102·6° before operation to 101° twelve hours and to 100° twenty-four hours after; the aspect of the patient improved, and she expressed herself as feeling much better. The only unfavourable symptom was the pulse, which, although its force remained good, maintained a frequency of 144 to the minute. Apart from the second perforation, nothing was found at the post-mortem examination incompatible with recovery, the peritonitis which persisted being limited to the exudation of plastic material over the viscera beneath the wound, which would, no doubt, had recovery ensued, have become converted into fibrous adhesions. 4. The unusual cause of death—perforation of a second ulcer. That this posterior perforation was quite recent and had occurred only a few hours before death was shown by the smooth, glossy condition of the peritoneal coat of the stomach around it, which, although intensely injected, was entirely devoid of lymph. The exact moment of its occurrence was not precisely indicated clinically as was the onset of the first perforation; but the patient complained of a return of the pain, and said she felt much worse on awaking at 8 A.M. on Nov. 9th, and it is reasonable to suppose that she was awakened by the occurrence of perforation, which will therefore have taken place within two hours before death.

Doncaster.

ADENOID GROWTHS IN THE PHARYNX.[1]



BY SIR WILLIAM B. DALBY, F.R.C.S. ENG.,
CONSULTING AURAL SURGEON TO ST. GEORGE'S HOSPITAL.

IN an article on the above subject, published in THE LANCET of Oct. 2nd, 1886, I suggested the use of a "steel finger nail" (a woodcut of which was appended) for the removal of adenoid growths and the complete clearance of the pharynx under an anæsthetic. Since this article was written the practice of removing these growths under an anæsthetic has become much more general than it was at that time (I do not for a moment imply in consequence of the article), and I notice in a recent work that the instrument which I there depicted is referred to as "*the* steel nail," so it may be assumed that it is favourably regarded and employed by other surgeons. I was especially careful at the time to explain the position in which the patient should be placed in order to ensure the impossibility of any blood being inhaled or trickling down the larynx and to avoid by this position any danger of asphyxia. It is even now worth while drawing attention to the fact that the position of the patient, as the pharynx is being cleared, is represented by two right angles, A to B being the head and trunk, B to C the pelvis to the knee, and C to D the knee to the foot, each leg being on either side of the narrow couch X to Z, on which the patient has been given ether before he is raised into the rectangular position. An admirably depicted drawing of a patient in this position was given in a paper by Dr. Hewitt and Mr. Sheild quite recently at the Royal Medical and Chirurgical Society. Why, therefore, it may be said, be guilty of repetition in

[1] Sequel to an article that appeared in THE LANCET of Oct. 2nd, 1886.

Digitized by Google

referring to this attitude apparently now recognised? Because unquestionably in consequence of malposition whilst removing adenoid growths several accidents (if such a term is allowable) have occurred, death being due to asphyxiation from the entrance of blood into the trachea. Also because after employing this rectangular position with the valuable aid of Mr. Braine for over nine years, both he and I can confidently say that no blood has ever been inhaled. In so saying there is no suggestion that this is the only position which is free from danger, as I am of course aware that several leading surgeons, who would permit no avoidable risk to a patient, employ two other positions which preclude any inhalation of blood. It is, however, natural that I, in advocating perfect safety to life, should select for emphasis the method which I have successfully employed and found more convenient than any other. The steel nail should, I think, always be used in patients after eight or nine years of age. In many children, when it is necessary to clear the pharynx before that age, and

especially before the age of five or six years, the growth is usually so soft that it is broken up and removed readily by the forefinger, using the natural finger nail for the purpose. This is, however, subject to exceptions. Thus, there is no doubt that adenoid tissue becomes the seat of hypertrophy in some children with a determined predisposition to it very soon after birth. I have occasionally seen children three or four years of age in whom the pharynx has been so filled with adenoid growth that in sleep they not only heavily snored but seemed in danger of choking, and when not asleep, especially when eating, snuffled and snorted in the most unpleasant manner. With them I have found that the adenoid growth was of the most tough consistence, and by no possibility could be removed with the finger nail. With them, also, it is not easy, owing to want of space, to move at once the steel nail around the pharynx, so that I have first passed into the pharynx the "curved ring knife"[2] and cut away large hard lumps of growth: then finished the clearance with the space thus obtained by the steel nail.

There is still another condition which requires mention, and which must have come under the observation of those who deal considerably with these matters. It is the greatly enlarged pharyngeal tonsil which occasionally alone occupies the pharynx, unaccompanied by adenoid growths, and exhibiting to the sensation of touch something quite different from the pharynx filled with adenoid growth, something of itself with a smooth surface, but none the less requiring removal in early life from its effects on nasal respiration. This also is very tough tissue and requires cutting away rather than scraping or scooping. Further knowledge derived from experience, information from varied sources, published accounts, or even hearsay, has so increased the interest in this subject that what was unknown in 1868 was recognised by a few in 1881, was then chiefly removed by Löwenberg's forceps in many sittings, and was subsequently removed in various ways under an anæsthetic, is now not only generally recognised by the medical profession, but talked about familiarly by the public as "adenoids." In short, the aspect of this matter is so changed that there is an appreciable risk of its becoming regarded by those who have no real knowledge as a universal inheritance of man. This idea of adenoids must have become very general with the public when children (in whom they are absent) are brought for their removal to relieve stammering and stuttering, or imperfect articulation due rather to failure in hearing or imperfect brain development. I have even known a lady over sixty years of age in whom it was proposed to "scrape her pharynx" for sub-acute catarrh of the middle ear. If an imagination can be so active as to suggest adenoids in an instance we may reasonably infer that some pharyn may, in the exuberance of zeal, be submitted to measures with questionable advantage.

Whilst regarding the abnormal amount of adenoid as a true hypertrophy which requires removal becau its interference with nasal respiration and as an exc cause of middle-ear disease, together with the fact the disappearance of this tissue commences and prog to completeness after the age of puberty, it naturally be anticipated that when the pharynx is at about the age of from ten to twelve years there be an end of the matter, and this is so. Now, if hypertrophy exists in a moderate degree in much life, the mischievous increase often takes place rapidly few months, and the exciting cause of the rapid is frequently an attack of measles, scarlet fever, diphth or whooping cough. Also, when in very early life the is cleared absolutely there will occur sometimes either or without these exciting causes a renewed activity. I we occasionally find a child, say, five years old, in wh growths have been removed, remaining perfectly fr several years, and active growth again commencing time before the arrival of puberty. These are the only cases in which a second operation becomes necessary, a is desirable that this occasional necessity be understo as to dispel any idea of an imperfectly performed opera

THE TREATMENT OF ACUTE INFLAMMATION OF BONE AND ITS JOINT COMPLICATIONS.[1]

BY WILLIAM H. BATTLE, F.R.C.S. Eng.,

ASSISTANT SURGEON TO ST. THOMAS'S AND THE ROYAL FREE HOSPITALS; FORMERLY ASSISTANT SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

THERE are few diseases which require greater accuracy observation and promptitude in treatment than the acute inflammation of the bones which occurs in children five years of age, and in those above that age when epiphyses have not yet united. I must touch briefly on diagnosis of the condition; its recognition is of the utmost importance, as the longer the inflammation continues without appropriate treatment the greater will be the local destruction of affected parts, the greater the tendency to involvement of the joint, and the greater the liability to pyæmia. Clinically three groups may be recognised. 1. Those cases which are almost certainly fatal from the first, owing to a general infection of the system, accompanied by high fever, great prostrlessness, and inability to sleep, with delirium, and the supervention of the typhoid state. If life is prolonged more than three or four days the bone inflammation is localised, as the signs of it have time to develop, for sometimes the bone disease is only found on careful search after death. 2. Those cases of a mild type in which the symptoms of bone inflammation are locally very evident, but the general disturbance is slight, and in which under appropriate treatment recovery ensues without any operation. The bone may, however, become thickened in the region of the epiphysis, and lengthening may follow in consequence of overgrowth. 3. To the third group I would include by far the largest number of cases, although they present great differences when a number are compared together. These cases may be sub-divided into other groups, but with little advantage. The great feature about them is this, that treatment may be successful in apparently the most severe. There is in all them a great danger of pyæmia, but much can be done to prevent it. In the worst cases there is the danger of infection, of involvement of more than one bone, of extensive necrosis of the bones attacked, and of death from hectic or from amyloid disease caused by the prolonged suppuration. The patients are, however, young, and it is often possible to save both life and limb in apparently desperate cases. W

[1] Abstract of a paper read before the Islington Medical Society Oct. 23rd, 1895.

acute necrosis of bone is spoken of it generally refers to those included in this group.

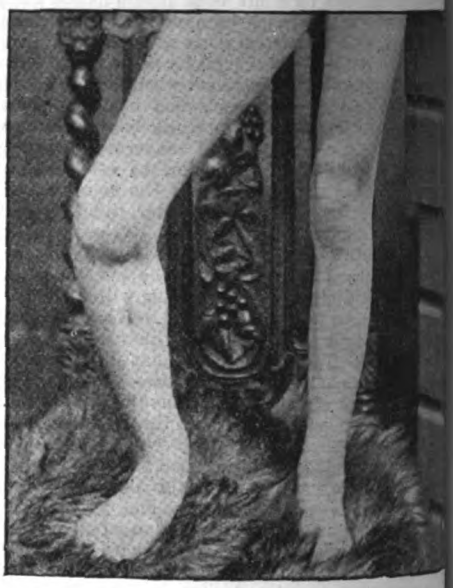
The most marked symptom is pain accompanied by fever. This pain is not, perhaps, easily localised at first, but gradually increases in intensity at night so that the child cannot sleep, or, indeed, move or permit anyone to approach without a cry of apprehension in the more severe cases. Swelling and œdema soon follow and are most marked near the epiphysis. The tenderness is acute, and delirium soon sets in. In severe cases the aspect of the child is one which I have never seen in any other illness, but so characteristic that it alone has enabled me to diagnose the disease correctly. There is a look of such utterly hopeless misery and suffering that the pale, drawn face, with sunken eyes, looks years older than it should do. The diagnosis is considerably helped by recollecting the character of the pain, especially its increased severity at night, for it is out of proportion to the pain met with in any other disease with which it may possibly be confused. I have seen cases sent to hospital for treatment for acute bone inflammation when there was nothing more serious than erythema nodosum, lymphangitis, or cellulitis present; but a fault more commonly committed is that of mistaking it for acute rheumatism and keeping the patient under treatment with anti-rheumatic remedies until almost irreparable mischief has been done. As a rule the character of the pain in acute bone inflammation, and the presence of swelling and tenderness over the bone and not over the joint, will suffice to establish the diagnosis, especially as there are none of the sour-smelling sweatings of the rheumatic state. Greater difficulty will sometimes be met with when a joint is involved early in the illness, but there will still be the œdematous swelling, the great pain, and unusual tenderness over the bone in which the mischief began, whilst the inflammation will be usually limited to one joint and its neighbourhood. When suppuration has occurred there is no longer any question as to the nature of the illness. The condition of joint disease which most closely simulates an acute inflammation of bone, with secondary involvement of the joint, such as that which I am considering, is gonorrhœal arthritis; but that is an affection of later life.

Having once come to the conclusion that the case is acute inflammation of bone, no time should be lost before energetic treatment is commenced. Leeches to the part, followed by hot fomentations, the application of a splint to the limb, and the administration of a sharp purgative, will relieve, if not arrest, the disease. If the patient is not seen until suppuration has undoubtedly set in, or if the previous treatment has not answered expectations and there is increased tenderness accompanied by swelling, an incision should be made over the most tender spot through the periosteum. Usually there will be a spurt of turbid fluid or pus, but if not it will be well to separate the periosteum in the direction of the epiphysial line, when similar fluid may escape. Fluctuation should never be waited for. In many recorded instances the application of a trephine to the end of the diaphysis has been most advantageous. All incisions should be made with antiseptic precautions; personally, I always wash out the wounds with 1 in 40 chloride of zinc solution, using perchloride dressings, and, if necessary, splints. Not only will early operation limit or even prevent necrosis of the bone, but it will also at times prove effectual in saving the neighbouring joint from invasion.

CASE 1. *Acute inflammation of humerus; early incision; recovery without necrosis.*—In the case about to be described the movements of the joint are perfect, the upper end of the bone is normal, and had it not been for the scar along the front of the shoulder, which is partly fixed to the bone beneath, it would have been difficult to understand that the patient had had a severe attack of periostitis. When aged fifteen he was under my care in the Royal Free Hospital for a month from May 4th, 1891, and this is the history of the case. Five days previously he had been throwing a cricket ball and felt a pain in the right shoulder. He went to work next day, but was obliged to give up as the shoulder was so painful. He had also had cold shivers and been unable to sleep at night in consequence of the pain. On the day of his admission he was carrying the right arm as a patient does who has a fracture of the clavicle. The shoulder was much swollen and very tender, and the outline of the joint was lost. He could hardly bear to be touched, but it was elicited that the greatest point of tenderness was at the upper epiphysial line of the humerus. He had walked to the hospital, but was pale and evidently suffering. His temperature was 101°F. Six leeches were ordered, also a good purge. The pain was less next morning, but returned towards midday, and he perspired freely. The arm was more swollen, the swelling extending nearly to the elbow. The most acutely sensitive spot was to the outer side of the upper part of the bicipital groove; here the skin was œdematous and shiny. There was also a pink flush extending up and down the arm for a considerable distance. An incision was made through the deltoid, and at the spot of greatest tenderness the periosteum was found to separate with unusual ease from the bone. Immediately above this, at the upper end of the diaphysis, an abscess containing about one drachm and a half of pus was opened. The bone was bare and rough at this part. The drainage-tube was removed on the 19th, and a rapid recovery was recorded. Considerable thickening was present over the upper end of the humerus when he left.

In most instances, when a patient is affected by this disease, it has its origin in the shaft of a long bone, usually the tibia, and the attachments of the periosteum to the epiphyses above and below prevent extension of the pus into the neighbouring joints. When the inflammation attacks the innominate bone in the neighbourhood of the hip there is not the same chance of limitation of the mischief, and early operation is imperative if the joint is to be saved. I think I may claim that early operation saved the joint in the following case.

CASE 2. *Acute inflammation of ilium; recovery without necrosis or involvement of joint.*—A girl aged fourteen years was sent to St. Thomas's Hospital on June 12th, 1889, and admitted under the care of Mr. Mackellar. It was stated that she had hurt her hip by falling against some railings a fortnight before, but on being questioned more closely she could not state that there had been no uneasiness about the part before that. She had been confined to bed for a few days with pain about the hip which was worse at night and on exertion. There was a decided fulness behind the left hip-joint on comparing the two sides, and much tenderness, this being most acute about an inch above and behind the hip-joint on the dorsum ilii. The femur could be gently moved and rotated without pain, but voluntary movement was very limited, and quick movements caused the joint to be fixed and the patient to complain at once. There was thus considerable resemblance to joint inflammation. At night the temperature was 103° F., and she suffered much pain. The morning after her admission I cut down on the most tender spot, divided the periosteum, lifted it with an elevator for a short distance towards the joint, and let out about half a drachm of pus. The bone was roughened at the site of the abscess. There was some discharge from the wound, and a drainage-tube was employed until July 9th. By July 30th the wound was soundly healed and the patient went home well. The case of a girl aged twelve years, who was brought to the out-patient department at St. Thomas's Hospital this year, further bears out my contention. She was taken ill two days before with pain about the left hip, and the only complaint was of pain in this situation when I saw her. There was no complaint of headache or anything else. The parts around the hip felt hot to the touch, and when the hip was moved she complained of pain, but gentle movement of the joint was well borne. There was considerable tenderness on pressure above and behind the joint over the dorsum ilii, but no fluctuation could be felt. She was sent into hospital at once on that day (March 19th), but no operation was performed until the 22nd, when fluctuation could be easily made out and pus was evacuated through an incision. The ilium was found to be carious. She left the hospital for a convalescent home on April 9th, the wound not having closed. She was sent back again on the 27th with septic arthritis of the hip-joint, for which excision was performed on the 29th, and she left the hospital again, well, on June 22nd.



CASE 3. *Acute inflammation commencing in pelvic aspect of acetabulum; early incision of abscess; extension of disease into hip-joint; dislocation of head of bone; excision.*—When the inflammation has its commencement on the pelvic side of the acetabulum the condition in its early stage is not only very difficult to diagnose but extremely difficult to treat. A little boy aged five years came under my notice in the out-patient department at St. Thomas's Hospital two years ago, and was at once admitted. Two days before admission, on Feb. 13th, he was noticed to be

Digitized by Google

restless in the evening; next day he had great pain across the abdomen and in the left hip, and was unable to put the left foot to the ground. The pain was becoming worse. The only history of injury was that of a slight fall on the day on which the illness began. Examination revealed nothing definite. There was pain on movement of the hip, but not severe, and some general tenderness, but not localised. He kept the thigh flexed and limped when walking. His temperature was over 101° F. Two days after admission, the patient being under chloroform, it was possible to discover fluctuation in a swelling situated about the point which corresponded to the acetabulum on the brim of the pelvis. His general condition had not improved. On the following day I made an incision above Poupart's ligament in its outer half, and opened the abscess by Hilton's method; it contained about an ounce of pus, but was a long way from the surface. From Feb. 20th to March 2nd the temperature was normal. Great difficulty was experienced in keeping the tube clear and the sinus open, and after March 2nd the temperature became more irregular, but never high. On the 13th it was found that pathological dislocation of the hip had occurred, and at the operation of excision of the head performed on the same day the acetabulum was found to be nearly filled with granulation tissue. As the disease had evidently spread through the bone, the bottom of the acetabulum was freely removed and a communication made with the pelvic abscess. A tube was passed through this opening from the old wound to the new. Here the extension of disease which was feared took place in spite of operation, and I regret to say that the boy died from pleuro-pneumonia of septic nature on April 10th.

The long period of rest which is necessarily enforced in this disease is usually followed by some stiffness of the joints of the limb affected. This is, however, easily overcome by passive movement and massage. Sometimes, without an actual invasion of the joint, inflammation may spread through the epiphysis, which becomes fixed, and if movement is not practised early and with perseverance a true ankylosis will ensue. The following case is a striking example of the difficulty which the treatment of such joints may present.

CASE 4. *Acute inflammation of tibia ending in necrosis; suppuration in tibio-fibular joint; sequestrotomy; ankylosis of knee.*—The patient, a girl aged five years, was admitted to St. Thomas's Hospital under the care of Mr. Mackellar on Feb. 21st, 1887, and remained in hospital until Oct. 11th of the same year. She began to complain of pain in the right leg on Feb. 16th, five days before admission, and swelling soon came on, which the mother had poulticed without affording relief. When she was admitted there were vivid redness and fluctuation over the upper half of the tibia, which was extremely tender, the patient being very intolerant of examination, and screaming on the slightest touch. She was flushed and feverish, with a temperature of 101·4° F. The same evening an incision three inches in length was made over the upper and inner part of the tibia and a large quantity of pus evacuated, which looked healthy and was without odour. The upper end of the diaphysis was completely stripped of periosteum for five inches. The line of the epiphysis presented a worm-eaten appearance. There was abundant discharge for some days, and the leg continued to be a good deal swollen and tender. On March 8th an abscess was opened behind the head of the fibula, and on April 13th another was incised behind the tendon of the biceps femoris. The superior tibio-fibular joint was evidently invaded. Two months after the commencement of the illness I removed the upper third of the diaphysis of the tibia after section of the bone with a chain saw. The upper end easily separated from the epiphysis. Although there had been great improvement in the condition of the patient, and she was able to eat well and had put on flesh, the amount of new formation of bone was very slight at that time. After extraction of the sequestrum a long hollow trough remained in which pus would have collected constantly, so a drainage-tube was passed from the bottom of it through the inner side of the limb. At first the leg was placed in a MacIntyre splint, but in the course of a few days it was found that in consequence of the softening of the ligaments of the tibio-fibular articulation, due to the suppuration in that joint, the muscles were causing a shortening of the leg, so an extension apparatus was applied above the ankle with a weight of one pound, and the new bone when formed took exactly the shape of the normal tibia, being moulded by the muscles, but it was a long time before this became united to the epiphysis. It was feared that ankylosis between the lower end of the femur and the tibial epiphysis might take place, so in June, before the 25th, when the union of the epiphysis and diaphysis of the tibia appeared to be firm, the patient was placed under chloroform, and an attempt made to move the knee-joint. This proved to be very difficult, for the epiphysis of the tibia formed a mere disc which could be moved by considerable pressure of the thumbs, but only to a limited degree, and attempts to utilise the leverage afforded by the shaft were useless, as the line of junction yielded at once. Movement was, however, carried out a few times before the patient was taken away by her father. He promised to bring her up to hospital regularly for this treatment, but it was only after his death, two months later, that she was again brought. The knee-joint was then firmly fixed, but in a good position. This girl was again under my care this year for a deformity of the leg, which is shown in the accompanying engraving (taken from a photograph). The limb was shorter by two inches than its fellow, and it was necessary to perform osteotomy of the tibia and fracture the fibula before the condition could be improved. The section of the tibia was made through the upper end of the diaphysis, and I took advantage of the occasion to excise the thin, adherent scar which is shown, and unite the subcutaneous tissue and skin in one long line over the raw surface left. The result is all that can be desired.

Condition before operation in 1886

No surgeon would view without great concern suppuration of a neighbouring joint during the progress of a case of acute inflammation of bone. It is a most serious complication. I am not sure, however, that a surgeon is not occasionally responsible to a certain degree in his supervision of the patient when this happens, for when the disease has extended across the epiphysial line and the part is bathed in pus, often of a septic character, a slight increase in the pressure of diaphysis against epiphysis will certainly lead to greater local destruction, and this ulcerative process may extend through the epiphysis into the joint. It is not necessary to apply an extension apparatus, but it is advisable to see that the limb below the seat of mischief is placed in such a position that its weight does not fall towards the weak point. Either by perforation of the epiphysis or by extension through the periosteum along the surface of the epiphysis, or by some other process, when a joint is invaded, the case should not be given up to amputation, but an attempt should be made to save the limb. In saying this I grant there are cases in which it would be advisable to amputate at once instead of trying more conservative treatment. But all cases should be looked upon as hopeful unless the condition of the patient, locally or constitutionally, is manifestly too bad to enable him to stand the drain of the necessarily prolonged suppuration. Even then the joint should be aspirated and the fluid drawn off-

Digitized by Google

t, this should always be first tried; sometimes it will ficient to cure: as in a case of inflammation of the tibia my charge this autumn, when the left knee-joint was ed, no reaccumulation of the fluid took place after apping. As the upper end of the tibia and the lower f the femur are the most common seats of this acute ive inflammation, the knee-joint is the one which is to be most often invaded. More than one joint however, suffer in the same patient, but the case d not be given up simply for that reason. patients who are sufferers from this acute bone mation will stand an amount of exhausting sup- ion which would kill an adult. So long as the ite continues good, the patient sleeps well, and emperature is not of more than a mild hectic type, the easing emaciation and apparent feebleness may be dis- ded. Some day the weary head will be lifted to h another child playing with his toys; it will be known the corner has been turned, and a rapid convalescence ensue. As the knee-joint is the one which is most ently affected, I should like to dwell more fully on the ment of the joint when suppuration has taken place in f the first aspiration has not been successful and fluid umulates, the aspiration may be repeated, but it must e expected that it will be curative; it will be merely a s of postponing the more serious operation of opening nd draining the joint. To do this most thoroughly al incisions should be made, and in some cases a rior incision also. The lateral incisions should be d on each side of the upper part of the joint, com- ed just behind the lateral extensions of the synovial h, and carried forward so that when a drainage-tube has passed across the joint it will form a segment of a without any irregularity or ledge on which pus can ct. Every case does not require a posterior incision, nany do require it, and whenever the temperature does all to a reasonable extent, and the local condition does apidly improve, it will be far the best plan to make one. incision at the back of the knee which I prefer is one h is carried down to the joint in the interval between the head of the gastrocnemius and the inner hamstrings. his incision all the structures really divided are the the subcutaneous tissue, and the posterior ligament e knee-joint—it is the line of safety. The reason why line was chosen by me in the first place was that I had nder my care for a time (in 1883) a man with suppura- of the knee-joint; the pus pointed in the position which nlarged semi-membranosus bursa usually occupies, only r down and nearer the tibia. After an incision into this which gave exit to a large quantity of pus, there was eed for further incision, as the pus discharged through opening, and the patient got well. I have had under my also a boy with traumatic suppuration in this joint, and s case, when I expected no further trouble, as the front ne joint was doing well and his general state was good, oscess formed and required opening in the situation just cated. There was no doubt in my mind that an earlier ion would have saved some days' illness. I could give r examples, but this will suffice. The mere making of ions will not of course do away with the need of other ment. The joint should be irrigated. Antiseptic sings are required and appropriate splints should be ied. The limb should be immobilised as much as ible and care taken that there is no undue movement of oint or limb when it is advisable to change the dressings. change of dressing should be made as seldom as ible, and with many children who are easily frightened upset it is a good practice to give a whiff of chloroform revent pain from startings of the limb, and also for any ipulation or incision likely to cause much mental distress haustion. It is well also in hospital practice to have consent of the parents to give chloroform whenever it be thought desirable without further reference to them. ne case this anæsthetic was given no less than twenty s. I have used the continuous bath with benefit to the ent, but do not like it, and only use it very exceptionally; position in which the limb is placed is awkward, the bath ires much attention, and the limb becomes œdematous, ested, and sodden.

is not often that a sound and movable joint can be ined when it has been drained for the relief of suppura- , but this should of course be the aim of the surgeon. the case of the boy present at the meeting the is perfect except for the presence of scars. Full flexion is permitted: the limb is well developed and without shortening.

CASE 5. *Acute inflammation of the tibia; involvement of knee joint; drainage of joint; sequestrotomy; acute inflammation of fibula; obscure cardiac symptoms; recovery.*—A boy aged eight years was admitted under my care to the East London Hospital for Children, Shadwell, on Sept 30th, 1890, and continued in that institution until the middle of January of the following year. He first complained of pain in his right ankle on Sept. 25th and said that it had been hit by a stone the day before. The ankle was swollen, but he was not taken to the hospital until two days later. Nothing definite was made out except that he could not fully flex the foot. It was placed on a back splint with a foot piece and an evaporating lotion applied. On the 29th it was thought that the bandage had been applied too tightly, as there was more swelling. That night he was delirious, and when he was admitted next day the swelling was much more extensive. At 5 P.M. the whole limb was much more swollen and red, the swelling being marked over the malleoli, and everywhere the tibia was exceedingly tender. There was thought to be some fluid in the knee-joint. Several incisions were made. As far as could be discovered the entire diaphysis of the tibia had been stripped of periosteum; there was also bare bone over the lower end of the diaphysis of the fibula. The next day he was much easier, but was tender all over, and a systolic murmur was present at the apex. The limb was placed in a carbolic bath. On Oct. 2nd he complained of pain about the left ankle, but nothing could be found to account for it; however, an abscess over the outer malleolus had formed and was incised within thirty-six hours afterwards. The drainage-tubes were taken out of the incisions in the right leg on the 4th. He was a little delirious during the day, and it is stated that a friction sound was heard over the cardiac base and that there was some increase of dulness to the upper border of the third rib and to just beyond the middle of the sternum. On the 7th there was some fulness over the right hip, with tenderness, but it was also noted that the abnormal dulness in the cardiac area and the friction sound had disappeared. The tenderness of the hip gradually subsided in two or three days, and his progress was satisfactory until the 20th, when the knee-joint became affected and had become so painful that it was aspirated the same evening and an ounce of turbid fluid removed. Aspiration was again performed on the 23rd and an ounce and a half of pus withdrawn. On the 24th the joint was drained through lateral incisions, a tube being placed across from side to side; this tube was removed four days later at the first dressing, but had to be replaced in a few days' time. The dead bone was removed from the tibia on Nov. 8th. It had been thought that a necrosis of the whole diaphysis had taken place, but only the anterior half of the shaft was dead. Dr. Eustace Smith examined the chest for me on Nov. 18th and considered the cardiac murmur to be a hæmic one. On the 25th all splints were left off. On Dec. 6th some small sequestra were removed from the right tibia and from the left fibula. By the end of that month no cardiac murmur could be heard. When the patient left in January of the following year he could voluntarily flex the right knee to a right angle. The cardiac symptoms were of much interest, for they are often of serious moment in acute inflammation of bone and imply a bad prognosis.

I would add a word of caution to those watching a patient with early suppuration in the knee-joint. Careful examination should be made from day to day to see if the area of the swelling is extending. Sometimes, as in the case the notes of which are appended, the upper margin of the synovial membrane will be found to be thickened, this line of thickening will be found extending further up the thigh, and the tension of the joint will be less; ulceration of the synovial membrane is taking place, and there is now an absolute necessity for incisions, as the pus will otherwise diffuse under the quadriceps extensor of the thigh. Occasionally the swelling of the knee will disappear rather suddenly, and, unless the surgeon is wary, he will think the patient better until he is confronted by a huge abscess of the thigh. This is not speaking too strongly, for I have myself had to open such abscesses on one occasion. The patient, a woman, had pyæmia, and when admitted both thighs were enlarged in front, and the abscesses extended from under the patella up to the hip-joint on both sides, and contained an enormous quantity of pus. The patience and amount of treatment which these patients may require, as well as some of the

Digitized by Google

important complications occasionally met with, are exemplified by the following case, which was under treatment for 299 days on the first occasion.

CASE 6. *Acute inflammation of tibia and os calcis; suppuration in knee, ankle, and big-toe joints; drainage of joints; sequestrotomy; albuminuria; recovery.*—A boy aged fifteen years was admitted to St. Thomas's Hospital under the care of Sir W. MacCormac on Jan. 2nd, 1888, and left on Oct. 7th. For three months he had had some starting pains and cramp in the left leg, chiefly at night, but there appears to have been no serious complaint until Dec. 25th. On that day he got down from an omnibus when it was going at full speed, and, although he was not aware of any injury at the time, in a few hours he noticed that the left ankle was swelling, and he experienced great pain in it. On his admission to hospital there was found to be a suppurative periostitis of the tibia, chiefly in the lower three-fourths, and two incisions were required to give exit to the pus, one in front of the inner malleolus, the other half-way up the tibia on the inner side. His temperature was 104° F. Ten days later there were sickness and diarrhœa, a good deal of discharge, but not much pain until about the 29th, when it was found that there was some evidence of suppuration in the ankle, and incisions were made which gave exit to pus. He also developed suppuration in the metatarso-phalangeal joint of the big-toe of the same limb. He did not at first obtain much benefit from these incisions, and they were enlarged. After this he improved until on March 31st sequestrotomy was performed and necrosed bone removed from the tibia. At various times sequestra of small size were removed from the os calcis and tibia without any ill effect; but on June 3rd, the day after an operation, a sharp attack of erysipelas developed. Until this date there had been no affection of the knee-joint, but soon afterwards, on the 8th, the knee was found to be very much swollen and tender, and an ounce of pus was withdrawn on aspiration. As the temperature was of a mildly hectic type and there was no starting of the limb, aspiration was repeated on the 12th and 15th, when six ounces and seven ounces were removed on the respective occasions. Although the general and local symptoms remained much the same, it was evident that the normal limit of the synovial membrane no longer formed the barrier to extension of the pus along the front of the thigh, and a firm raised line could be felt; ulceration had evidently taken place, and the abscess was spreading. Lateral incisions were made, as also one behind in the line of the semi-membranosus bursa, on June 7th, a tube being placed across the joint between the lateral incisions, and another in the popliteal one. The patient complained of a good deal of pain on the following day, but within ten days the temperature was normal, and on July 7th there was no pain when the dressing was changed. On July 15th the urine was smoky and albuminous, and mixed hyaline and granular casts were present, with blood cells. He had a pasty appearance, and there was still discharge from the various wounds and from a splint sore under the heel, but the last tube had been removed on the 7th. The evidences of renal disease passed away, and on Sept. 13th there was no albuminuria. The wounds were healed, although the limb continued to be enlarged, and the os calcis and tibia were thickened. He was readmitted in the following year, and a cavity in the upper part of the tibia, which had not then closed, was scraped and afterwards healed by granulation. The knee was kept slightly flexed and was quite ankylosed.

CASE 7. *Acute inflammation of femur; suppuration in hip-joint; excision of hip; sequestrotomy; disease of humerus; recovery.*—A girl aged twelve years was admitted to St. Thomas's Hospital under the care of Sir W. MacCormac on Nov. 28th, 1885, and remained in the ward until April 5th, 1886. On Nov. 19th she had made a false step in going upstairs and jarred her hip. The upper part of the thigh had gradually swollen and become very painful on attempted movement, and she had been unable to sleep. The signs were those of an acute suppuration of the hip with well-marked fluctuation. Her temperature was 104° F. The patient was very ill. On the morning of the 30th her condition was as follows. She had slept very little either night since admission and was very restless and delirious, talking constantly. She was quite sensible during the day. The tongue was furred and dry. There was no sickness, and she took liquid nourishment fairly well. She looked pale. Her temperature in the morning was 102·8° There was no rigor. The pulse was 116 and full. The right hip-joint was flexed, with marked outward rotation, and there was great swelling around the whole upper third of the femur. The iliac fossa was free. There was fluctuation over the front of the hip, with extreme tenderness on pressure over the great trochanter. The pain was great, but not so great as on her admission. The left elbow was flexed, with very moderate swelling; pain and great tenderness existed over the lower end of the humerus, in the posterior aspect of the elbow, and spreading up the arm. There was a sharply marginated bright red-patch. She also complained of pain in the right shoulder, where there was a little swelling with some tenderness, especially in the posterior aspect. Langenbeck's hip incision was made on the 30th, much pus flowing away before the capsule was incised. I could pass my finger quite round the neck of the bone, which was bared, especially on the anterior aspect, and for four inches down the shaft. The joint contained very little pus. The upper end of the femur was removed after section below the great trochanter. Incision was also made above the left elbow, and some pus evacuated which came from a cavity, at the bottom of which was bare bone, extending a short way up the shaft. On Dec. 10th the right elbow was painful, and there were slight swelling about the lower epiphysis of the humerus and some bright redness over the elbow, with pain on movement. A splint was adjusted. On March 1st a large sequestrum was removed from the upper end of the femur. When she left the hospital there were from two to two and a half inches of shortening; there was free voluntary movement at the hip, which was in a good position, with slight outward rotation of the femur. There had been no necrosis of the humerus on either side, and the wound was healed.

The majority of the cases have done well after incision, and there has been no complication of importance. Ulceration of an artery caused by the pressure of a drainage-tube was met with in one case and nearly proved fatal. It is certainly an accident to be guarded against, especially at the ankle-joint and lower part of the thigh.

CASE 8. *Acute inflammation of tibia; suppuration in ankle-joint; incisions; hæmorrhage from posterior tibial artery; sequestrotomy; recovery.*—A little girl aged nine years was admitted under the care of Mr. Mackellar to the Elizabeth Ward of St. Thomas's Hospital on Oct. 15th, 1886, and was discharged on June 1st of the following year. The illness commenced definitely on Oct. 8th with lameness owing to pain in the ankle and shivering fits; her appetite failed, and she was unable to sleep. Hot fomentations were applied by direction of her medical attendant, and she had been kept quiet, but swelling and redness of the lower part of the leg showed themselves, and she was admitted with well-marked osteo-periostitis of the right tibia, with suppuration limited below by the epiphysial line of the bone. Incisions were made the same day and the pus was evacuated. The lower three-fourths of the bone were denuded of periosteum to a varying extent. On the 27th there was pain in the right ankle-joint and she was very fretful at night, but on Nov. 11th there was suppuration in the joint, which was opened on each side, and a drainage-tube was passed across, some pus being evacuated. The condition of the joint improved, but on the 22nd there was profuse hæmorrhage into the dressings, which were saturated, and the patient showed the effects of the loss of blood severely, being sick and restless, with a low temperature. The wound was plugged, and on the following day when she had rallied I ligatured the posterior tibial artery at the ankle above and below a large opening into it. Before ether was administered her pulse was 180. Sequestrotomy was performed on Jan. 16th, 1887, and on April 6th a small piece of bone was removed. The big-toe was very stiff and partly flexed on the latter date, so it was forcibly straightened and afterwards kept in position by a loop of drainage-tube, which was also passed round the ankle. She left for a convalescent home when there was merely a small sinus. The ankle was fixed in a plaster-of-Paris splint, which she wore for some time. When seen a few months later there was some ulceration of the scar tissue over the lower end of the tibia, but she could walk very well.

I have purposely refrained from discussing the somewhat difficult question of diagnosis from pyæmia; the relationship between the two diseases is very close, and the discussion of the subject would take more time than I have at my disposal. It is in my experience not unusual to find a patient complaining of pain in a joint distant from the seat of the

Digitized by Google

bone inflammation, which becomes red, swollen, and œdematous, but does not suppurate, and in time recovers without any incision.

I must express my thanks to the surgeons whose names have been mentioned for their permission to treat, and now to publish, the cases which have been noticed.

Mansfield-street, W.

WHY IS THE ABDOMEN OPENED IN THE MIDDLE LINE?

BY F. WINSON RAMSAY, M.S. DURH., F.R.C.S. EDIN.

IN text-books on abdominal operations the linea alba is always recommended as the proper site for the incision, or, in default, the linea semilunaris. From this fact and from the unanimity of opinion which appears to be held by operators on the subject, one would naturally suppose that there must be some great advantages to be obtained from opening the abdomen in one or other of these situations. On inquiry I find they are as follows: (1) vascularity is low in the middle line, and therefore the hæmorrhage is less; (2) there are fewer and less important structures to cut through; and (3) there is greater facility of access to all parts of the abdominal cavity. As regards (1) this advantage is imaginary and is really a disadvantage, for, although the abdominal wall is more vascular in other situations, yet there is never any hæmorrhage in incising the abdominal wall elsewhere but what can be easily and speedily controlled, and, moreover, it is this absence of vascularity which tends to delay rapid and permanent healing, and therefore predisposes to hernia. (2) is also a disadvantage, for the whole depth of the incision being through tendinous or fibrous layers having a great similarity to one another renders it difficult, especially to young operators, to know exactly the depth of the incision. This is especially the case when there has been inflammatory action. It is difficult to get the layers exactly together again, and they always cohere, so that the depth of the scar when formed is barely one-eighth of an inch thick. This is noticed especially when making an incision through the scar of a previous incision. (3) is the only valid argument that can be used in favour of the median incision, and, as I can show, is theoretical rather than practical.

A disadvantage of the median incision is that should it be necessary to extend it upwards the umbilicus comes in the way, and as it cannot be rendered aseptic with certainty it has to be avoided and the incision deflected, while some operators remove the umbilicus entirely. This being so, is there any situation in the abdominal wall which offers further advantages without these disadvantages? I think so, and that the ideal incision for abdominal section is one vertically through the middle of the rectus muscle on either side, and for the following reasons: (1) although the parts are vascular there is no hæmorrhage; if the epigastric artery is cut, it is easily secured, and this vascularity tends to rapid and efficient healing; (2) there is no injury to the muscle, for after the fascia is divided the muscular fibres are easily separated with a director and retracted; (3) the incision can be made in any part of the muscle and continued up to the ribs or down to the pubes in the same manner; (4) the umbilicus gives rise to no inconvenience; (5) the layers are so well marked that it is impossible with ordinary care to wound the viscera; (6) access to all parts of the abdominal cavity is just as easy as in the middle line (this I have found from experience, whilst in some cases, where tubal or ovarian disease is known to be only on one side, it is an advantage to have the incision slightly on that side); (7) the scar left looks as if there had been a skin incision only—it does not pucker or dip in like the ordinary scar, and the separate layers are not coherent; and (8), most important of all, if the wound is properly closed the risk of hernia is reduced to the least possible minimum. The best method is to close the wound with silkworm-gut sutures, running through all the layers. These are placed *in situ* and held by forceps; then the peritoneum and posterior layer of fascia are brought together with fine silk sutures, either continuous or interrupted, and then the anterior layer of fascia in the same manner. This brings the muscle firmly together, making the passage through its fibres valvular, restores the natural thickness of the abdominal wall, and prevents coherence of the fascial layers, leaving the abdominal wall in as good a condition as before the operation. Should temporary drainage be essential, the necessary sutures should be placed *in situ* and marked with knots. They can then be drawn and tied accurately when the tube is withdrawn. Even if drainage has to be continued for some time, the track running through a thick wall will close better and more firmly and be less likely to give way afterwards. I have adopted this incision during the past two months in five cases—viz., two ovariotomies, one tubal gestation, one pelvic abscess, and one cholecystotomy—and have found that these advantages claimed are real and practical. I am convinced that if some surgeons of higher standing than myself would give this matter their careful consideration this incision would be generally adopted, and that students would be taught that the one place to be avoided in opening the abdomen is the linea alba.

Bournemouth.

A SEVERE CASE OF FOOT-AND-MOUTH DISEASE OCCURRING IN A BOY.

BY WILLIAM BLIGH, M.D., B.S. LOND.,
LATE HOUSE SURGEON, GUY'S HOSPITAL.

UNFORTUNATELY, this case was not seen until the fifth day of the disease, the history up to that time gleaned from the mother being as follows. The patient, a healthy schoolboy aged thirteen years, was quite well until July 18th. On the morning of that day he complained, while eating, of some soreness of the mouth; he did not feel ill, and went to school as usual. On the 19th the soreness was worse, and the mother noticed some swelling of the lips, with "little lumps" on their insides; the eyes also became inflamed. On the 20th blisters were noted in the mouth and a few itchy spots appeared on the hands; the mouth was very sore, and the patient was given alum and water to wash it with. On the 21st and 22nd the mouth became more painful and more spots came out on the hands. Up to this date the boy was feeling fairly well; but on the 23rd he became feverish, dull, and listless, and I was asked to see him. I found him in the following condition. He was evidently very ill—pale, listless, and apathetic. The pulse was markedly slowed (fifty-four per minute); the temperature at 5.30 P.M. was 104° F. The lips were considerably swollen and covered with ruptured vesicles showing bases grey with heaped-up epithelium. The tongue was thickly coated with grey epithelium, which on being scraped away showed irregular, raw patches. The tongue itself was not swollen. The hard and soft palate showed circular grey patches with surrounding injection; these patches had coalesced on the hard palate, forming an irregular serpiginous outline like one sees in herpes affecting this region. On the left of the swollen uvula there were two, and on the right one, such circular patches, and a few also on the anterior pillars of the fauces. The gums, pharynx, and insides of the cheeks were free. There was great fœtor of breath and constant dribbling of serum and saliva. The eyelids presented an appearance closely resembling an ordinary eczematous blepharitis, there being dried muco-pus adherent to the margins and conjunctivitis limited to the neighbourhood of the lids. At the junction of the skin and mucous membrane at the left ala nasi there was one vesicle, but the mucous membrane of the nares was unaffected. On each hand there were many vesicles, mostly about the size of a goosequill in section, containing clear serous fluid, and each surrounded by a narrow zone of hyperæmia. They were distributed almost entirely on the palms of the hands, palmar surfaces of the fingers and backs of the two distal phalanges. The coronæ were especially affected, the vesicles here being smaller and tending to run into each other, while beneath the thick courticle of the palms and palmar surfaces of the fingers they were very numerous, but discrete and not raised. The backs of the hands were quite free, and there were none on the wrist or forearm of the left hand, but the right wrist had three on its flexor and one on its dorsal aspect.

Digitized by Google

The number of vesicles may be judged by the fact that I counted forty-seven on the right hand alone. The toes were quite free, but there were two or three scattered vesicles over the metatarsals on either side. The rest of the body was free. There was no glandular enlargement and no abnormal physical sign to be discovered in any organ. The urine was normal. The patient was given a mixture containing perchloride of iron, sulphate of quinine, and chlorate of potash, the mouth ordered to be frequently washed out with dilute Condy's fluid, the eyes to be bathed with boric acid solution, and some yellow oxide of mercury ointment to be smeared along the lid margins. He was ordered plenty of fluid nourishment, with two glasses of port daily. On the morning of the 24th he presented a most striking clinical picture, plunged in sleep so profound that he was with difficulty aroused, the lips swollen and pouting, saliva constantly dribbling from the mouth, and muco-pus exuding from the eyelids. He, however, took nourishment freely on being awakened, but immediately relapsed into deep sleep. The morning temperature was 102·6° and the pulse 56 per minute. He was ordered a purge and the local treatment to be continued energetically. Three capillary tubes were filled from some of the vesicles on the hands and forwarded to the Clinical Research Association for bacteriological investigation. (Their report is added.) On the 25th drowsiness was still marked, two or three of the vesicles on the fingers had become hæmorrhagic; the bowels had acted well and the breath was less offensive. The morning temperature was 102° and the pulse 55. On the 26th there was slight improvement generally, the tongue tending to clean; the appetite was returning, and the boy began to take some interest in his surroundings. The morning temperature was 100° and the pulse 55. On the 27th there was marked improvement, the lips were showing healthy granulations, and the tongue was clean, showing islets of intact epithelium standing out on a raw background. The vesicles on the hands, where situated beneath thin skin, were becoming opaque, and where beneath thick skin were drying. The morning temperature was 99° and the pulse was still only 54 per minute. On the 28th the lad was quite bright; the lips and tongue were healing; slobbering only took place during sleep; the vesicles on the hands were drying up without suppuration, and the eyes were nearly well. The temperature was 99° and the pulse 52. Convalescence was now rapid, and in a few days he was quite well, the slow pulse being almost the last symptom to disappear. The diagnosis presented no difficulties; if one makes a list of the various diseases characterised by vesicles we should have variola, varicella, vaccinia rash, syphilis, herpetic fever, foot-and-mouth disease, eczema, herpes, erythema bullosum, pemphigus, cheiropompholyx, scabies, traumatism, and hand-and-mouth disease of Hutchinson. From amongst these, foot and mouth disease is picked out by the distribution and character of the rash, its life history, the association of hand and mouth, the absence of prodromal fever, a history of previous varicella, and, finally and conclusively, by the results of the bacteriological investigation. The source of infection remains a mystery. The cows on the estate on which the boy's father lives and those belonging to the dairy from which the family's milk supply is obtained were alike free from disease, and no sheep, pigs, or donkeys in the neighbourhood were, as far as I could ascertain, affected, nor had the boy been employed in looking after any such animals.

[The following is the report of the Clinical Research Association:—

"Microscopic examination of the serum in the three tubes submitted to us after appropriate staining gave the following results. In two of the tubes the serum contained cocci, arranged in pairs and as staphylococci, but with some few streptococci. In the third, however, the streptococci preponderated. These organisms were isolated by means of plate cultivations, when the staphylococcus was found to present no marked differences from the staphylococcus epidermidis albus described by Welch as being a common inhabitant of the skin. The streptococcus presented the following characteristics. The organism grew well, though rather slowly, on all nutrient media except potato (on which the growth was extremely scanty). The growth in streak cultures consisted of minute, transparent, jelly-like, spherical colonies, not confluent, and not making their appearance until forty-eight to sixty hours after inoculation. Microscopically, it occurred in long, wavy chains of from thirty to fifty members, the individual cocci being grouped in pairs and somewhat smaller than the ordinary streptococcus erysipelatosis. It stained well with the aniline dyes and was not decolourised by Gram. From a consideration of these points we have no doubt that we are dealing with the particular pathogenic streptococcus Klein described as being the cause of the foot-and-mouth disease among cattle, &c.—CHAS. H. WELLS, Secretary."

Caterham Valley.

NOTES ON A CASE OF

HÆMOPTYSIS AS A COMPLICATION OF TYPHOID FEVER; RECURRENCE AND DEATH.

BY A. G. M. CREAGH, M.R.C.S. ENG., L.S.A.,
MEDICAL OFFICER, CAPE COPPER COMPANY, LIMITED.

THE occurrence of severe and fatal hæmorrhages from the lungs in a non-phthisical patient during the course of typhoid fever is apparently a rare complication, no mention of it being found in the last edition of "Quain's Dictionary of Medicine" or in the works of Hilton Fagge, Burney Yeo, or Bristowe. The notes of the following case may therefore be of interest as occurring in the course of a disease so widespread as enteric fever.

The patient was a man aged thirty five years, healthy and well developed, who had had no serious illness with the exception of an attack supposed to have been rheumatic fever, contracted in Norway. There was no evidence of cardiac enfeeblement or abnormality. He was first seen on Sept. 15th at 1.30 P.M., with a temperature of 102·3° F., accompanied by shivering and malaise. On Sept. 16th and 17th the temperature ranged between 101·5° and 102·2°. On the 18th the temperature at 10 A.M. was 101·2°, and at 8.30 P.M. 101·8°. A slight amount of bronchitis in both chest fronts was present, and inspiratory and expiratory sounds were loud and rough. On the 19th, 20th, and 21st the evening temperature reached 103·8°, falling in the mornings from half to three-quarters of a degree. The pulse ranged from 118 to 120, and the respiration was 24. There was no increase of vocal resonance, dulness, or bronchial breathing in any region, but a limited expectoration of a glairy, sticky nature, occasionally slightly tinged with blood. There was a thick mucoid accumulation in the nostrils, which was removed by the patient's efforts with great difficulty, and which at times consisted of blood clots, arising from a congested state of the mucous membrane. On the 21st there were gurgling and tenderness in the right iliac fossa, followed by gradually increasing abdominal distension. On the 24th (the tenth day of the illness) rose-coloured spots appeared on the abdomen, and considerable meteorism was present. The evening temperature was 103·8°. On the 25th the morning temperature fell to 101·2°, rising in the evening to 102·4°. At 2 A.M. on the morning of the 26th the first attack of hæmoptysis occurred, consisting of about two ounces of bright aerated blood. A second attack took place at 5 A.M., and a third and more severe hæmorrhage at 8 A.M., when the temperature fell to 98·4° and the patient became cyanosed, with respiration 38 per minute and the pulse 120 and feeble. The seat of hæmorrhage appeared to be chiefly in the right front, gurgling in the bronchi being heard over a large area of the right lung and less so over the left. The hæmorrhages were checked by turpentine, ergot, sulphate of alum, and dilute sulphuric acid. The patient's condition was most critical, and at my request he was seen in consultation by two neighbouring practitioners. Ice was given freely by the mouth, digitalis was added to the medicine, the usual routine treatment of hæmoptysis was pursued, and the administration of turpentine and digitalis continued every four hours. During the day the patient rallied, his temperature rising to 101·2° at 9 P.M. and the pulse slowing to 98. The respiration was 28. At 1.15 A.M. on the 27th I was called and found that a fourth attack of hæmoptysis had set in with increasing dyspnœa: not more than one ounce and a half of blood were expectorated. The remedies previously successful were again administered and a hypodermic injection of ergotin was given but without effect, and the patient, choked by the bleeding, died at 2.15 A.M. The treatment throughout the case was by Dr. Burney Yeo's mixture, with the addition of small doses of wine of ipecacuanha. Two scruples of salol in powder were given in twenty-four hours, together with a diaphoretic cough mixture, during the early part of the illness when the bronchitic symptoms were most troublesome.

Remarks.—Although epistaxis is so common a symptom in typhoid fever, hæmoptysis appears to be very rare. Doubtless they both depend upon the lessened coagulable power of the blood in this disease, and in forming one's prognosis it is well to bear in mind the possibility of such an occurrence amongst the many other complications to be feared. The

Digitized by Google

above case was neither phthisical nor a hæmophiliac. There is strong evidence to prove that the disease was conveyed through the milk-supply coming from an infected house where there were four cases of typhoid fever. The milk was not boiled before use, and a second inmate of the patient's house also contracted enteric fever. Some others to whom the milk had been supplied were protected by previous attacks; in other cases the milk was regularly boiled. In these latter no bad results have appeared as yet, a point in favour of the advisability of boiling milk.

Ookiep, Cape Colony.

THE MORTALITY FROM EMPYEMA IN CHILDHOOD.

BY J. P. WIGHTMAN, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE SENIOR HOUSE SURGEON, INFIRMARY FOR CHILDREN, LIVERPOOL.

IN this condition, a serious and not uncommon one, a favourable prognosis may be given, providing that the diagnosis is made in the early stages. What can be more sad than a mother bringing her child, worn out by prolonged hectic due to a discharging empyema, for advice? The rapidity of convalescence, averaging from six to eight weeks, and the usual cure, no trace of the disease remaining, add a special attraction to a condition which, if left alone, must almost always produce a fatal result. The subject of this disease and its treatment has been brought forward in the various medical journals, this paper being in part a *résumé* of the various views and methods of treatment.

Signs of a recent attack of scarlet fever (desquamation &c.) are by no means uncommon in patients seeking relief at a children's hospital. With regard to this, it is remarkable that among 1008 cases of scarlet fever, mostly in children, recorded in THE LANCET during the year 1891 empyema is not even mentioned as a complication; nor is this the case in a paper on Scarlet Fever published in Vol. XXI. of the St. Thomas's Hospital Reports. This naturally leads one to infer that empyema is most likely to occur if a case of scarlet fever is neglected. Various statistics of mortality are on record. The younger the patient the greater the risk of a fatal termination. The sooner the purulent effusion is removed the quicker the recovery. Rupture of an empyema through the chest wall or into the lung is a grave complication, though the latter occasionally leads to spontaneous cure. Apart from the above, danger to life is chiefly threatened by the onset of complications—viz.: (1) pericarditis (among 29 fatal cases at the Liverpool Children's Infirmary[1] pericarditis occurred 12 times, in 10 it was of the suppurative form); (2) peritonitis; and (3) septicæmia.

As regards the effect that different methods of treatment have, taken as a whole, I do not think resection of rib renders the chance of cure either greater or less, except in certain cases. At the Hospital for Sick Children, Great Ormond-street, from 1880 to 1892, 214 cases were treated. Of these, 85 were treated during the earlier period by incision, with 16 deaths, and 129 afterwards by resection of rib, with 23 deaths, the mortality, as will be seen, being nearly the same in each case.[2] Mr. Godlee published in 1886 the result of 36 cases. The majority (19) were treated by resection, the remainder by incision or aspiration. Of these cases only 1 was fatal. In THE LANCET of May 5th, 1894, I published the results of 118 cases, classifying all treatments together, with 23 deaths. In the same journal[3] Dr. F. E. Batten of London published the results at the Hospital for Sick Children, Great Ormond-street, for the year 1893-94. Of 43 cases treated by resection, 5 were fatal. In THE LANCET also he asserts strongly that resection is the only treatment for empyema, a statement which I think cannot be accepted without much reserve. Dr. E. Cautley of London, at a meeting of the London Medical Society,[4] in a paper based upon a series of 86 cases treated by various methods, gave a mortality of 16·6 per cent. The rate of mortality was the same after resection as after incision, with the exception that 5 out of 6 cases under two years old, treated by resection, were fatal. His opinion was that resection ought only to be had recourse to in cases in which the tube could not be inserted without, when drainage was imperfect, or for the cure of an old sinus. Dr. Morison of Hartlepool (34 cases, 2 deaths) upholds incision.[5] By the courtesy of Mr. Jordan Lloyd of Birmingham I am able to publish the treatment and results at the Birmingham and Midland Children's Hospital for the last five years. The total number of cases treated was 123; of these, 99 were cured, 20 were fatal, and of 4 there are no records. Among children of three years of age and under there were 43 cases; of these, 18 ended fatally. In the 99 cases cured the average stay in hospital was seven weeks and a half, the shortest stay eleven days, and the longest 164 days. Resection of rib was performed in 6 cases. I am indebted to Mr. H. G. Davis, house surgeon of the hospital, for taking much trouble in the preparation of the hospital statistics.

The routine treatment is incision and drainage as soon as pus is determined. Resection of rib is exceptional as a primary procedure.

If the above figures are put together they number 656 cases of empyema in children, with 104 deaths, giving a death-rate of 16 per cent.

The extreme gravity of empyema in a young child may be seen by the following:—

Mortality from Empyema in Children three years old and under.

	Cases.	Deaths.
Dr. Goodhart (Guy's Hospital Reports)...	29	19
Birmingham Children's Hospital	43	18
Liverpool Children's Hospital	35	18

These figures give a death-rate of a little over 50 per cent.

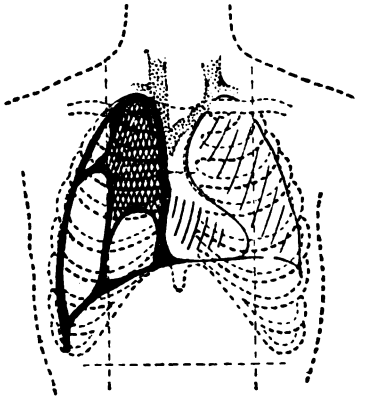
ROYAL FREE HOSPITAL.

CHRONIC RIGHT-SIDED PLEURISY WITH CONSTRICTION OF THE SUPERIOR VENA CAVA SIMULATING INTRA-THORACIC TUMOUR; REMARKS.



(Under the care of Dr. H. SAINSBURY.)

THE symptoms to which malignant growths of the chest give rise are very variable, depending upon the starting-point of the disease, whether pleura, bronchial tubes, or lung tissue. As these symptoms may be for a long time only those of a simple inflammation of the part attacked, this difficulty in diagnosis will be readily appreciated. The results which inflammation in its several stages and manifold incidence may bring about constitute an almost infinite variety of combinations. Here is an instance in which the diagnosis of intra-thoracic tumour, probably new growth, was made with some confidence, and yet the result of the post-mortem examination proved this to have been a mistake. The changes produced by the inflammation were unusual and extensive, but they were in no way the result of tumour formation.

A woman aged sixty-two was admitted into the Royal Free Hospital on Nov. 22nd, 1894, suffering from dyspnœa (of the variety orthopnœa), with much cyanosis and cough. She stated that she had suffered from winter cough for some years, that her present cough had been worse since the taking of a chill some six weeks before admission, and that her breath had become very short, especially of late. Two weeks before entering the hospital she said that she had noticed some blood mixed with the expectoration. Since the chill—i.e., during a period of six weeks—she was conscious of having wasted and lost strength. On examination the evidence of fluid in the right pleura was found; but though the chest on the right side was dull and

Digitized by Google

resisting from top to bottom both back and front, the position of the heart's apex beat showed little, if any, sign of displacement of the mediastinum. The liver edge was felt well below the costal margin, but upon this as a sign of depressed diaphragm one could, of course, not rely. Accordingly the dulness in degree and extent seemed to be in excess of that which an effusion could account for. The cyanosis mentioned was marked and accompanied by a pronounced anastomotic enlargement of the veins over the anterior surface of the trunk. Clearly there was obstruction of the superior vena cava. The chest was tapped and a small quantity of dark, sanguineous fluid withdrawn. The quantity which came away, under fifteen ounces, was wholly inadequate to relieve a distended pleura, but it was all that would flow off by syphon action, and, under the circumstances, all it was thought wise to try to get. The relief obtained was but slight, and in the course of a week or ten days paracentesis was again performed, with a similar result, but a rather smaller withdrawal; the fluid removed had the same dark, sanguineous character. The dyspnœa and cyanosis increased, the patient grew progressively weaker, and she died on Dec. 22nd, one month after her admission. Throughout her stay in hospital the temperature curve was apyrexial. There is nothing of importance to add in the way of history. The patient had scarlet fever when aged fifteen years and rheumatic fever when aged twenty. The family history threw no light on the case. At the necropsy, which was held on Dec. 24th, the right pleural sac was found to be converted into a cavity with thickened, rigid, almost cartilaginous walls, in which the same sanguineous fluid was found which on two occasions had been withdrawn in small quantity. Both layers of the pleura, parietal as well as visceral, were equally affected, and the mediastinum towards its dexter aspect shared in the thickening. The right lung pressed upwards,

inwards, and backwards, and, occupying perhaps one-third or one-fourth of its normal dimensions, was tied at two or more spots to the parietal pleura by stout cord-like processes of cartilaginous consistence. Towards the apex, in the vertebral groove and against the upper half of the mediastinum, the lung was adherent. Tracing the large veins from the root of the neck downwards into the chest, their dilated channels were found to maintain their patency till at their confluence in the superior vena cava where they entered the mediastinal thickening. The constriction here was such that the channel was reduced to a narrow, slit-like aperture admitting about a No. 5 catheter. Nothing in the shape of a tumour was discovered, and the mediastinal sclerosis causing the constriction was exactly similar in character to, and in no sense demarcated from, the general pleural thickening. The rigid-walled right pleural cavity could not have been under any tension from the fluid it contained, and it is more than probable that the exudation was a passive one from the congested intercostal veins, which followed, but scarcely pressed upon, the receding lung, as its thickened capsule (peripulmonitis) contracted upon the lung sponge work. The reason for the inadequate tappings now became quite evident: it would have been as feasible to drain a full beer barrel without a vent-peg as to empty this cavity by single aspirating puncture. No disease was found in the carnified tissues of the right lung, but the expanded left lung, which projected slightly across the mid-line, showed a hard knot on the outer surface of its upper lobe, with some surrounding puckering; there was no caseous centre to it.

Remarks by Dr. SAINSBURY.—It may be well to summarise the chief points upon which the diagnosis in the above case rested; they were the age of the patient, the latency of origin of the symptoms or their insidious onset, the accompanying loss of flesh and strength, the presence on at least one occasion of some blood in the expectoration, the dulness in excess of the evidence of fluid, the sanguineous character of the exudation, and, above all, the evidence of intra-thoracic local obstruction to the venous circulation. This group seemed to warrant the conclusion which was arrived at—viz., intra-thoracic tumour, probably malignant, with secondary implication of the pleura. Dr. Walshe, I am told, used to say on occasion that he had given up guessing; he probably did not mean this; but, face to face with the innumerable possible combinations of disease, even a shrewd guess may at times hardly be hazarded.

NORTH-EASTERN FEVER HOSPITAL.

A CASE OF SCARLET FEVER; OTORRHŒA; THROMBOSIS OF THE LATERAL SINUS; PYÆMIA AFFECTING RIGHT ELBOW AND LEFT HIP; RECOVERY.

(Under the care of Dr. F. M. TURNER.)

SEVERAL cases have been recorded during recent months of septic thrombosis of the lateral sinus occurring during an attack of acute suppurative otitis media. As a rule in such cases there is a history given of a chronic discharge from the ear, or of an offensive smell which is found to depend on old-standing disease without the escape of an appreciable quantity of discharge. In this case operation was required within a month after the discharge commenced. It is also remarkable for the few signs which were present at the time of the operation on the sinus, more especially the absence of any swelling, fulness, or tenderness over the jugular vein in the neck, although there was an increase of discharge from the opening in the bone on pressure over the vessels. There can, we think, be little doubt that the suppuration in the joints was pyæmic and resulted from the ear complication. The suppurative arthritis of scarlet fever usually shows itself about the third or fourth week, and although in more than one of the fatal cases thrombosis of the internal jugular vein has been noted it has not resembled that which is described here. The pain in the mastoid preceded the rigor, and the joint complications appeared the day after the operation, possibly caused by disturbance of clot during the necessary manipulations. The advantages of early incision of the joints are shown by the result. There is no doubt that a free incision with washing out is the best treatment for a pyæmic joint, and that harm is done by delay.

A slightly built boy aged six years was admitted to the North-Eastern Fever Hospital on Jan. 31st, 1895, suffering from scarlet fever. He developed the first symptoms on Jan. 27th, and the rash on the following day. During the whole of February he remained in a very serious condition, with a foul throat, swollen cervical glands, a nearly continuous high temperature, a small amount of albumin in the urine, and great muscular weakness. He became extremely emaciated though he took a fair quantity of fluid food. Feeding was very troublesome owing to his bad throat, but forced feeding through a tube did not become necessary. Otorrhœa developed on the right side on Feb. 8th, and on the left a few days later. Towards the end of the month his temperature was rather lower, but very irregular. On the 26th it remained below 100° F. the whole day, and Dr. Turner thought he had slightly improved in strength and seemed more comfortable. On March 2nd, however, the temperature again rose to 104°, and he vomited three times. He complained of pain in his right ear; he had hardly spoken a word the whole time he had been in hospital, and this was the first occasion he gave any useful information. Two days later he had a rigor lasting ten minutes, with a temperature of 104·8°. The pupils were unequal and remained so for some weeks later. The optic discs were normal, and there was no further vomiting. The diagnosis lay between two diseases, either of which would produce the symptoms observed: (1) acute interstitial nephritis or septic nephritis, a form which frequently accompanies the cases of scarlet fever complicated with

Digitized by Google

excessively foul throat; or (2) mastoid disease with intra-cranial extension, probably thrombosis of the lateral sinus. The first of these is often present without producing any great change in the urine, only a trace of albumin being found, and in particular without suppression or marked diminution of the quantity excreted. On the other hand, such symptoms as headache, vomiting, strabismus, drowsiness, irritability, head retraction, convulsions, &c., which point to cerebral disease, are sometimes produced by it, though subsequent post-mortem examination shows either no cerebral disease or else simple œdema. In this case the rise of temperature on March 2nd, vomiting, pain in one mastoid, and the rigor on the 4th, as well as the unequal pupils, were thought sufficient signs of mastoid disease to justify operation. At this time both ears were freely discharging pus which smelt offensively in spite of treatment. Neither pressure nor percussion on either mastoid was painful, nor did there seem any tenderness on pressure over the great vessels on either side of the neck. The only point which determined the side to be operated upon was the pain previously complained of behind the right ear. On the following day (March 5th) ether was given and the right mastoid antrum opened with a gouge. It lay about half an inch deep and did not contain pus, nor did it seem in any way abnormal. The bone, however, exposed in the posterior part of the hole was dark coloured. On working backwards the discolouration increased until the sigmoid groove was reached. On opening this a gush of dirty-brown fluid escaped, with a fetid odour not unlike that of fæces. Similar fluid continued to escape, at times with regular pulsation, and at other times in irregular gushes, the cause of which Dr. Turner did not at once perceive, but after a time he noticed that they depended on pressure being made on the neck, thus showing a communication between the fluid in the exposed intra-cranial cavity and the jugular vein in the neck. On discovering this, further pressure was avoided in that region as far as possible, for fear of driving septic material into the collateral veins. At first the accumulation was thought to be extra-dural, but it was subsequently found that it was in the cavity of the sinus itself. The sigmoid groove was first exposed at the bend, and at the anterior part of this the bone was not covered by dura mater. The posterior part, however, showed a layer of dura mater with a free edge running vertically and rather thickened; the most anterior part was almost black, but a little further back the membrane was adherent to the bone, and when exposed was of a red colour. The cavity was found to contain nothing beyond the brown fluid and a small loose slough or two composed of tough fibrous tissue; on exploring with a probe it led only in two directions, corresponding to the anatomical direction of the sinus—viz., from the bend of the sigmoid almost straight backwards for an inch, and from the lower end of the wound downwards and inwards as far as the jugular bulb. The dura mater forming its floor was ragged, but no opening into the posterior fossa could be found. At the later stages of the operation blood oozed up from the lower track, especially after accidental pressure on the neck. Owing to the pulse beginning to fail and the length of time already spent (over an hour and a half) the idea of ligaturing the jugular vein was abandoned, and the operation was completed by removing some bone between the antrum and the sinus and snipping off the above-mentioned black edge of the dura mater with scissors. The middle fossa had been exposed while opening the antrum and was seen to be healthy. The wound was gently syringed and dressed. On the night of the 6th he complained of pain in the right elbow, and on the next morning it was very swollen. On the following afternoon (March 7th) the right internal jugular vein was exposed and tied opposite to the cricoid cartilage. It was perfectly healthy as far as was exposed in the wound. The mastoid wound was then re-examined; some more bone was removed in order to lay it more freely open, after which some clot, together with a little yellow pus and dirty fluid similar to that seen before, was taken out. Finally, the elbow was opened by a long incision, syringed out with perchloride of mercury lotion (1 in 2000), and drained. On the 8th he complained of pain in the left hip, but the signs of pus were not sufficiently definite to make an operation advisable until the 12th. Though there was some fulness around the joint it was impossible to make a thorough examination owing to his serious condition, and movement was so free that the presence of pus was doubted. When it was at length decided to operate every arrangement was made for sewing up the wound should the capsule of the joint be found not distended. On the evening before the operation, although the patient screamed with fright if one attempted to touch the leg, yet he could be induced to move it himself through an angle of nearly 90°. However, on the 12th the joint was opened by the anterior incision, and a good deal of turbid and flaky fluid evacuated. The joint was then syringed and drained. On the next day the right gluteal region was found swollen, and Dr. Turner's colleague, Mr. F. C. Ford, let out an ounce or two of fæcal-smelling pus from an abscess cavity between the glutei. Owing to his serious condition no anæsthetic was given. The elbow healed very quickly. The tube was removed on March 18th, eleven days after the incision, and the wound was closed on April 9th. There was at no time after the operation any limitation of movement, and the joint is absolutely as good as before his illness. The hip, however, gave much trouble, whether from the pus having lain four days in the joint instead of twelve hours as in the case of the elbow, from the dressings getting fouled several times, or from imperfect drainage through an anterior incision it is difficult to say. Dr. Turner was forced to make a counter-opening posteriorly on March 28th, and to operate again on April 13th for inefficient drainage, and healing was not complete until June 2nd. Meanwhile, dorsal dislocation had appeared. A weight extension could not be used until seven days after the operation and had several times to be omitted, on one of which occasions dorsal dislocation came on insidiously. The last time that dislocation occurred was on May 10th, previously to which the joint had been in good position for a week or two without any support of extension. To prevent relapse he wore a Thomas's splint for twelve weeks. The course of the mastoid wound was interesting. The floor of the cavity, consisting of dura mater, came forward and gradually obliterated it, but caused retention of pus in the track formed at the lower end of the sigmoid sinus. On May 20th about a drachm of pus was let out and a tube rather more than an inch long passed down this track until stopped by bone. The next day it was found that pressure over the anterior triangle of the neck caused pus to flow freely from this tube. This observation was repeated the following day, but owing to the risk of driving pus into collateral channels it was not afterwards repeated. The abscess, however, eventually emptied itself without any counter-opening. The wound made for the ligature of the vein had already healed by first intention. On May 25th a further operation was required on the mastoid to remove several pieces of dead bone which had not become loose. The wound finally healed on June 22nd. Although syringing through from the antrum to the middle ear was quite free and was regularly performed for more than a month after the first operation, the otorrhœa returned immediately after the channel closed up, and persisted in spite of the total loss of the membrane and ossicles. He was last seen on Aug. 4th, having worn the splint until two days previously. He could walk well, and there was no sign of dislocation of the hip and no shortening. Movement was free in all directions. Both ears were discharging. He had got quite fat—a great contrast to his previous condition.

Remarks by Dr. TURNER.—The points in this case which strike me as being most unusual are—(1) the very slight signs which accompanied so extensive and acute an intra-cranial lesion; (2) the destruction of much of the wall of the lateral sinus, causing its contents to simulate an extra-dural abscess; (3) the healing of a long tortuous abscess by drainage through the mastoid wound, although it extended through the jugular foramen into the neck; and (4) the large amount of voluntary motion retained in the hip when distended with pus. Several of my colleagues helped me in dealing with the difficulties of this case, but I must specially thank Mr. J. E. Beggs and Mr. F. C. Ford for assisting at the numerous operations and for giving valuable advice.

ROYAL BRITISH NURSES' ASSOCIATION.—The first sessional lecture of the season was given on Friday, Nov. 22nd, at 8 P.M., at the offices, 17, Old Cavendish-street, W., by Dr. Louis C. Parkes, on the Importance of Breathing Fresh Air. The annual conversazione will be held on Monday, Dec. 9th, at 8.30 P.M., at the Institute of Painters in Oil Colours, Piccadilly.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues, as in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, &c.

AN ordinary meeeting of this society was held on Nov. 26th, the President, Mr. HUTCHINSON, being in the chair.

The PRESIDENT introduced the discussion, defining its scope and aim. He began by remarking that the brilliant discoveries which have rewarded the labours of experimental pathologists during the last twenty years have opened to the clinical observer many new trains of thought. Amongst them undoubtedly one of the most important is the recognition of parasitic germs as the causes of disease in a far wider sphere of action that was formerly believed; maladies which our predecessors were content to ascribe to constitutional proclivities, inherited tendencies, or to external influences quite unconnected with infection have now been shown to be attended by parasitic organisms. It has been proved in many instances that these organisms are capable when inoculated of producing the malady in question. The natural assumption has been that in most instances these organisms are introduced into the blood or solid tissues only shortly before beginning to manifest their presence. This conclusion has, however, seemed somewhat inconsistent with a considerable class of observed facts which would suggest that what we witness is often the result rather of matters which had been laid up in the tissues than of new contagion. It has therefore appeared to the council of this society that it might be opportune to discuss the whole question of possible latency. To prevent misconceptions it may be well to explain that the term "latent" is intended to apply only to periods during which, presumably, no vital activity is displayed. It is not to include incubation periods, and still less stages during which prodromata or early symptoms are present. A homely, or more correctly a rural, illustration will, said the President, if you will allow me to use it, best convey what is meant. For some years I had a field under cultivation in which poppies always grew amongst the corn. This field was laid down in grass, and during the eight years that it was pasture not a single poppy ever appeared upon its turf. Lastly, a part of the middle of this field was ploughed up and planted with trees. The ploughing was in winter, but next summer, without the possibility of the introduction of a single new seed, the whole plot grew a beautiful crop of poppies. Clearly the seeds had been latent for eight years; they had during that period retained their life, but had manifested no vital activity whatever. It was, indeed, in this absolute suspension of all attempt at development that their safety had existed, for had they once commenced to germinate they would infallibly have died. The process of growth once commenced could not have been arrested with impunity. Now, making all allowance for the wide difference between the seed of a flowering plant and the spore of a microscopic fungus, it is wished this evening to ask whether there is any reason to believe that parasitic microbes which infect the human body can in any way imitate the conduct of the poppy seeds, and under conditions not favourable to their growth retain their vitality in a state of absolute quiescence and, as far as observation from without is concerned, of latency. If such latency be possible, what are its limits in each instance, what are the conditions which favour it, and what are those which bring it to an end? In the instance of the poppy seed we know that nothing more than the advent of adequate warmth and moisture is required to start germination, whilst the final result may be modified by many other conditions, such as the constituents and character of the soil. Have we before us any facts, or any hints as to probable facts, in respect to parallel agencies in the case of infective microbes? Such is the inquiry before us to-night. It is scarcely necessary to remark that our topic is one of the utmost importance. Upon our knowledge in respect to the possible latency of germs will often depend the measures which we take for the prevention of infection, as well as those by which we hope still further to repress their activity. It may be, indeed, that a very large fallacy underlies much of our present creed as to infection, and that in many instances what we attribute to fresh infection is really consequent upon some change in the conditions of the subject which have favoured the development of pre-existing germs. Those who have worked most in the matter will, I suspect, be the readiest to admit that we are as yet but on the threshold of our knowledge as to the relationships which may exist between the cell elements of the body and parasitic germs or their products. If, in the instance of tuberculosis and erysipelas respectively it should in future seem probable that the germ elements necessary to their causation may remain long latent in the tissues, and may in such condition be transmitted from parent to child, important light will have been thrown on the accidents which follow vaccination. Without doubt both erysipelas and scrofulous affections do not infrequently seem to be set going by that, in itself, trifling procedure. It may be that we have been too much in the habit of accusing an unclean lancet or accidental infection of the pock, when all the while the disease was hidden in the infant's tissues and waiting only for suitable conditions to develop its activity. I wish to anticipate the criticism that we have taken too wide a field for this discussion. Without doubt diseases which are by no means closely cognate have been placed together in our list, and equally without doubt any one of them might have furnished sufficient material in itself for a debate. It has been thought, however, that as the subject is comparatively a novel one it was better in its first instance to approach it broadly, in the hope that facts supplied by one topic might throw light on those of others. Thus, from the consideration of hydrophobia we obtain one very remarkable fact, that whilst in most instances the poison begins to show its effects within six weeks of its introduction, in a few it may remain latent for eighteen months or possibly for several years. I am justified, I think, in using the term "latent" here, instead of speaking of a prolonged incubation period, for the facts favour the supposition that the poison is absolutely quiet during almost the whole of the period for which in certain cases the appearance of the disease is delayed. The real incubation period is probably the same in all, and in these cases does not commence until long after the introduction of the poison. It becomes of great interest, with this recognised fact in mind, to ask whether any similar instances of delay are ever observed in syphilis or other diseases due to inoculated specific poisons. Respecting syphilis itself I must not anticipate what Mr. Ernest Lane will presently bring before us, excepting on a very few points. I feel sure that he will pardon me for saying the problems in respect to it are of exceptional difficulty. At the same time I am sure that they place some of the facts as regards the possible latency, not only of active and living germs, but of cell tendencies originated by them but persisting long after their death, in a most instructive light. I may suitably, in connexion with syphilis, ask permission to introduce a distinction between true latency and a latency which is only apparent. It is highly probable that many children born with taint never show any evidence of it, and that some also of those who acquire syphilis never exhibit anything but the primary sore. In the case both of the infant and the adult thus apparently escaping there is probably no real latency, but only an absence of obvious phenomena. In each instance the blood changes are experienced, and in each there will ensue a liability to tertiary phenomena. It would be an instance of true latency if in such cases it were possible for the patient to manifest for the first time, at the end say of two or three years, an outbreak of secondary symptoms, but such facts are probably unknown. Leprosy finds itself in our list because of certain important facts which have been observed as to the length of time which may sometimes intervene between the date of its subject having left the place of presumed acquisition and the first appearance of outward phenomena. That this interval may be one of many years appears to be an established fact. Dr. Abraham has been good enough, at the request of the council, to undertake to bring before the society a critical examination of the evidence and to discuss its bearings. Although there is yet much difference of opinion as to whether leprosy arises from articles of food or solely from contagion, there is none as to the general fact that it does not now take origin in our own land. We are entitled, then, to assume, when a man who has lived in a leprosy district and having subsequently

Digitized by Google

resided many years in England in a state of health ultimately shows signs of the disease, that in some way the implanted germs or the induced proclivity, phrase it as we may, has really been existent in a latent condition during the interval. It must, however, be clearly understood that the facts with which Dr. Abraham will have to deal are probably very exceptional. The close relationship which probably exists between leprosy and tuberculosis makes all that can be proved as to the former of great value in reference to its more common, and for us in Britain more important, congener. Dr. Kingston Fowler will explain to us the facts and possibilities in respect of this latter topic, and the council regards itself as fortunate in having secured the assistance of one so well qualified for the task. Presuming, however, from his synopsis that Dr. Fowler will restrict himself very much to the physician's aspect of the question, I may venture to remark that much light may also be hoped for from certain groups of facts which are more likely to fall under the cognisance of the surgeon. Most especially is it desirable to enlist the coöperation of those engaged in the observation of diseases of the skin. To them opportunities will occur for observations of a kind which can be equalled in no other department of practice. Tuberculosis of the skin can be studied in all its stages and in its very various forms more easily than tuberculosis of any other structure. I will, if you will permit me, very briefly advert to some of the lessons which lupus vulgaris appears to teach. Everyone will, I suppose, admit that this malady is in some way associated with the tubercle bacillus. Now, it would appear that there is in the very beginning of lupus vulgaris a stage of active self-infectiousness. During this stage the patient may develop patches of lupus on various parts of the body at great distances from each other. This stage, however, is short; a few months or a year, and after that the liability never recurs. The patient may go through life with one or more patches of lupus steadily aggressive at their borders, but apparently wholly without power of infecting distant parts. This, it will be seen, is the exact reverse of what occurs in cancer, in which the infecting area is usually for some time solitary, and multiplicity goes on increasing with the progress of the disease. It cannot be said, however, even in cases in which single patches of lupus remain single through a long life (and such are common enough), that the germs which infect are absolutely quiet or that they are really latent. Their presence is throughout obvious enough, and they still exhibit the power of infecting the tissues in close contiguity to them. More than this, however, they cannot do, and it seems clear that they have undergone some modification which in some marvellous manner restrains their activity of development. No dermatologist fears for his patient with one or more patches of lupus vulgaris of long standing that they will either induce visceral tuberculosis or cause additional outbreaks on the skin; a sort of half-latency appears to have been attained. I cannot but think that these facts may prove of great assistance in reference to our speculations as to tuberculous processes in general. Lupus has, however, yet more to teach us in reference to the laws of latency. We encounter certain cases in which the disease has been cured by treatment in early life, and in which recurrence takes place in old age. Two such I may mention as examples. In each a young lady had been cured, by the vigorous use of caustics, of lupus affecting the nose. In each the cure was complete so far as external appearances went, nothing but the healthy scar remaining. In each instance the patient married, became the mother of children, and passed through life in good health and without any tendency to recurrence of the lupus. In both, after the lapse of more than thirty years in one case and nearly forty in the other, the disease did finally again develop itself in close proximity to the original patch. Is it reasonable in such cases to suppose that a second infection had taken place? Is it not much more probable that germinal matter—bacilli in some sort of cell partnership—had remained undestroyed, and that when in senility the vital forces again became enfeebled they were able to again assert their vital powers? We seem here to have proof of latency of infective material during very prolonged periods. To complete the picture I may add that in both these cases the recurred lupus was well characterised, and proved, as lupus in old persons often does, very intractable. Allusion has already been made to erysipelas and to the possibility of its microbe being long latent, and even transmissible. As we have no one in the list of those who will open this debate who has undertaken to deal with this topic, it is perhaps desirable that I should add somewhat to what I have already suggested. It is much to be desired on many of the topics to be mentioned this evening that the experience of the clinical observer should be carefully collated with the facts ascertained in the laboratory, but in none is this more requisite than in respect of the maladies which go under the name of erysipelas. The streptococcus discovered by Fehleisen has been cultivated by many and used for inoculations repeatedly, not only on animals but on the human subject. That it is capable of producing an erysipelatous type of inflammatory action there can be no doubt. What its relation may be to the various forms of disease which the clinical observer recognises as erysipelatous is, however, a very difficult question. According to Fehleisen, the period of incubation is exceedingly short, often only a few hours, and this fits in with what is observed when in surgical practice contagion can be traced, and particularly with outbreaks of erysipelas in vaccination practice in which, the arm of the vaccinifer being inflamed, disease is conveyed to many infants at the same time, and in all shows signs of development within twenty-four hours. There does not appear to be any evidence that the incubation period of inoculated erysipelas is ever protracted; far less that there is ever any stage which could be considered one of latency. The numerous instances of erysipelas after vaccination which reveal themselves on the ninth day or later are to be referred to exciting causes other than poisoning at the date of the operation, and in support of this it may be stated that they are usually isolated. The facts which suggest the belief that the erysipelas microbe may assume latency belong, not to its original introduction, but to what happens to the patient long after the first attack. Some of these are strongly suggestive of the belief that this virus, once admitted, comes to stay. It would appear that in some cases those who have had erysipelas once are liable to it ever after. So long as their tissues are exempt from injury they are free, but at any time an abrasion, an operation wound, or even possibly exposure to heat, cold, or chemical irritants may bring on an attack. Thus it may develop after a carefully conducted operation, and beneath complete antiseptic dressings. It is difficult to believe that in all the cases of this kind which have been observed fresh contagion had occurred. The creed that they are rather instances of the survival of latent germs derives support from another and yet more numerous group of facts. In elephantiasis the first attack of œdema is often ascribed to erysipelas from some slight injury, and unquestionably the patient continues ever after liable to recurring brief febrile attacks attended by all the local phenomena of a mild erysipelas. The same statements are true of not infrequent cases of recurring inflammation of the face which result in solid œdema. Some doubt will possibly be felt as to the suitability of discussing the natural history of such a disease as ringworm in company with diseases so different as are most of the others on our list. It is possible, however, that although the fungus here concerned is of a higher class and of very different development, yet the laws concerning its growth and possible latency may not be wholly dissimilar. Most dermatologists, I think, now hold that alopecia areata is in all probability, in at least some of its forms, a cryptogamic disease and a close congener of true ringworm. Now it is well known respecting this latter that the hair may grow again and fall again at long intervals, the cause of its falling having apparently a tendency to submit to conditions of absolute quiescence. Other observers go so far as to believe that alopecia is a result of ringworm, and that it usually begins after many years during which the parasite has been wholly latent. Although these are for the present little better than mere conjectures, yet they supply, I think, in relation to other parts of our subject, material for instructive comparison. Nor is it without probability that were we to pass on from ringworm to the fungal parasites which attack other vegetables and dead animal matter, we might learn other important lessons as to the modes of life of this class of plants. It would not, I believe, be at all difficult to show that under many circumstances it is customary for them to pass into conditions of quiet and inactive existence which may be very prolonged. I must not, however, venture on this theme, nor must I occupy any more of your time. It is proposed that at the end of this meeting the discussion shall be adjourned, and that it shall be concluded at our next. This evening we hope to take all the introductory papers which have been announced, and if this is accomplished, on the second evening the debate will be in the hands of the Fellows. It will be

considered that all the subjects mentioned in the programme are open for consideration and comment.

Dr. WASHBOURN said that two points in the life history of bacteria were of interest in connexion with latency. The mode of growth of certain bacteria in broth was analogous to the varying incubation period in specific diseases; under favourable conditions growth occurred at once and rapidly reached its maximum, but with the reverse conditions the growth was deferred. The next point was in reference to the resistant forms assumed by bacteria under unfavourable conditions. Spores were well-known examples, but even sporeless bacteria were capable of producing resistant forms. As an example he quoted the pneumococcus. Probably bacteria when latent in the body existed in this phase of their development. He believed some of the clubbed shapes assumed by the diphtheria bacillus represented resistant forms. The pathogenic bacteria protected themselves against the bactericidal influences of the body by means of their toxines. Saprophytic bacteria were devoid of this means of defence, and were easily destroyed when introduced into the body. The experiments of Wyssokowitch were quoted. Saprophytic bacteria injected into the veins of animals at once disappeared from the blood and accumulated in the organs, and in twenty-four hours were completely destroyed. The resistant spores of the hay bacillus, however, remained alive in the organs as long as seventy-eight days after inoculation. The difference between "toxic" and "septic" diseases was described. In toxic diseases the chief aim of the body was to protect itself against the action of the toxines, while in septic diseases the object was to destroy or hinder the growth of the bacteria. Both factors were present in all cases of immunity whether natural or acquired, but either may be the principal mode of defence in either type of disease. The tissues of the fowl were poison-proof to the tetanus toxine, and hence the bacilli were destroyed like saprophytes. In animals immunised to diphtheria and tetanus the antitoxic substances developed in the fluids of the body annulled the effects of the toxines, but had no influence over the growth of the bacteria. It was for this reason that diphtheria bacilli could remain latent in the throats of healthy individuals without producing harm. The body was poison-proof, but the bactericidal properties were not sufficient to destroy the bacteria. Sometimes, especially in animals immunised to septic diseases, the bactericidal properties were much increased without a corresponding increase in the antitoxic properties. He quoted the example of hog cholera. Pathogenic bacteria when introduced into the tissues of immune animals were sometimes rapidly destroyed, the pneumococcus in forty-eight to sixty hours in the experiments of Emmerich. But as a rule destruction was more tardy. A number of instances were given. Trapeznikoff found living anthrax spores in the tissues of a frog 100 days after inoculation, and Welch found living typhoid fever bacilli in the gall-bladder of a rabbit four months after intravenous inoculation. Latent bacteria were either englobed in cells or prevented by a barrier of cells from gaining access to the rest of the body. An attempt to shut off the bacteria from the circulation was made even in the case of highly susceptible animals, as in the experiments of Werigo. In relapsing fever the spirilla were shut up in the cells of the spleen during the apyrexial stage. The reason why latent bacteria were often missed by microscopical examination might be because they were converted into forms which were not easily recognised. The transformation of cholera vibrios into oval-shaped bodies in Pfeiffer's experiments was quoted as an example. The return of activity of latent bacteria was discussed, and the investigations of Trapeznikoff and of Baumgarten mentioned; also the effect of tuberculin and mallein in awakening into activity latent tubercle and glanders. Dr. Washbourn mentioned his own experience with latent forms of rabbit septicæmia which were brought into activity by inoculation with other bacteria. The bacteriological evidence of latency of germs in the human body was then discussed and a number of examples given. Diphtheric bacilli, pneumococci, streptococci, gonococci, and tubercle bacilli had been found on the mucous membranes of healthy individuals without producing any ill-effect. Babes had reported a case of acute glanders probably contracted six years previously; and Schnitzler one in which the staphylococcus aureus had apparently remained latent in a bone focus thirty-five years. Some of the cases were possibly due to a reinfection, but this interpretation was excluded in cases where living typhoid fever bacilli had been found in osteomyelitic foci long after recovery from an attack of typhoid fever. Several instances were quoted, of which the most notable were those of Sultan and Burchke. In the one case six years, and in the other seven years, after an attack of typhoid fever living bacilli were found in bone abscesses.[1]

MEDICAL SOCIETY OF LONDON.

The Operative Treatment of Cleft Palate.—Distribution of Motor and Sensory Symptoms after Injury to the Roots of the Brachial Plexus.

AN ordinary meeting of this society took place on Nov. 25th, Sir JAMES CRICHTON BROWNE, President, being in the chair.

Mr. EDMUND OWEN read a paper upon the Operative Treatment of Cleft Palate, based upon five cases which he had operated on in private in the early summer of this year. One operation was on an infant aged eight months whose cleft implicated the back of the hard as well as the soft palate. The result was perfectly successful. He urged that the operation for cleft palate should be performed at the earliest available moment, so that the voice might be harmed as little as possible. Of one of the reported cases he showed a plaster cast as well as a water-colour drawing. The former demonstrated the fact that in front of the soft palate the cleft measured seven-eighths of an inch in width; the latter revealed through the cleft the presence of an enlarged pharyngeal tonsil, constituting the disease known as adenoids. This tonsil was cleared away before the palate was operated on, but there was a failure in securing union of the soft palate. All the other operations turned out successfully. (We propose to publish Mr. Owen's paper in full in a subsequent number of THE LANCET.)—Mr. J. H. MORGAN said that he cordially agreed as to the precautions of an antiseptic nature which it was advisable to take in cases of cleft palate, but the wound was of necessity so exposed to the atmosphere that an aseptic condition could not be maintained. He discussed the question of the age at which operation should be undertaken. Mr. Clutton's paper had prompted him to operate upon clefts of the soft palate at an earlier period than he had been hitherto accustomed to do. His experience of this early operation was confined to three cases, and, unlike Mr. Owen, he had not met with success. He was therefore still inclined to advise that in clefts of the soft palate the operation should be deferred until after the eighteenth or twenty-fourth month, because before this the child was usually weakly and could not easily absorb nourishment, which had to be administered by artificial means. Then the troubles associated with teething had to be taken into account. He preferred not to operate until the canine teeth had erupted, and he chose the period between this and the time of molar eruption. If this period were not chosen the surgeon should wait until after the molars were through. With careful instruction the bad habit of speech could be corrected after closure of the palate later in life, and he quoted a case which illustrated this. As to closing the hard palate, the operator must take his chance, selecting the first favourable period after the completion of the first dentition. Formerly the time chosen was between the sixth and seventh year, but now probably the average age was from three to three and a half years. It was remarkable how much more successful these operations were in private practice, the frequent breaking down of the wounds in the hospital being probably due to the germ-laden condition of the hospital air. The dry accretions of mucus on the pharyngeal wall would serve as resting-places for micro-organisms, and they should therefore be removed.—Mr. CLUTTON did not think that the time of closure should depend upon whether the hard or soft palate was affected, as it was easy to close both. The height of the palate should rule the question of early operation, for if the palate were high it would come together much more easily than a horizontal one. The thick palates united far better than the thin ones. He preferred to do the operation at about six months of age, and at any time after this up to the age of three. Nothing was gained by waiting after this, though he had operated at the age of twenty-six. The improvement in the voice would depend greatly upon the total antero-posterior length of the palate when closed. He advocated fishing gut and horsehair rather than silver wire

[1] The report of this interesting debate will be continued next week.

for suture. A large amount of failure was due to want of relieving tension by free incision at the sides of both the hard and soft palates. He never opened the child's mouth until a week after the operation, and he always removed all the stitches, giving an anæsthetic for this purpose if the child was under the age of twelve months. He had seen the stitch-holes become larger if the sutures were left.—Mr. D'ARCY POWER asked what was the best operation to be done in very flat arches. He had adopted the method described by Mr. Davies-Colley, but with an unsatisfactory result. The private cases probably did better because the children were of better stamina.—Mr. DAVIES-COLLEY said that he operated much earlier than the age given by Mr. Morgan; he preferred operating at the age of fourteen months, using the flap method he described eighteen months ago. His further experience of this operation was that he got union of the hard palate readily, but it was not so favourable for the soft palate. He had never found any difficulty in drawing over a flap in the low-arch cases. Since he read his paper before the Royal Medical and Chirurgical Society he had operated on three cases aged between fourteen and seventeen months. He obtained in two complete union of the hard palate and considerable union of the soft. The third case was difficult, as the child had been operated on for harelip previously, and the mouth was very small; he unfortunately cut the base of the triangular flap, which afterwards melted away. He only used the ordinary operation for older children now. If the operation was done early the cleft was not only closed before the child began to talk, but deformity of the face, with wide separation of the cheek bones, was avoided.—Mr. ARBUTHNOT LANE said the important principle in operating in these cases was to have plenty of room, and for this reason the harelip should be left till after the palate had been closed. He had often split a united harelip to get more room. He had devised a gag which kept the mouth well open and gave a maximum of room.—Mr. WALSHAM said that he made a lateral incision, separated the inner periosteum rapidly with an aneurysm needle, and pared the edges last. He held that the ateral structures should be very freely divided until the palate hung perfectly flaccid. He made it a rule not to look into the mouth until the end of a week.—Mr. KELLOCK said that he had observed many such children both before and after operation. At the Hospital for Sick Children the patients were usually admitted five to seven days before operation in order to allow them to get accustomed to their surroundings. The accumulation of hard secretion on the back of the pharynx was favoured by mouth breathing. He related a case in which a cleft palate was associated with single kidney. The opposite organ was slightly hydronephrotic, and the child died after operation from suppression of urine. Children were worried by rectal feeding, and it was better if they could swallow to feed them by the mouth. The improvement in speech after operation was often very slow.—Mr. OWEN briefly replied.

Dr. BEEVOR described two cases of Injury to the Roots of the Brachial Plexus. In the first case a man aged twenty-five was caught by the right hand in the strap of a gas engine and thrown off his feet on to his back two years ago, and was paralysed directly after in all the muscles of his right arm, excepting the small muscles of the hand and the flexors of the thumb and fingers. When seen three months later he had also lost some power in the latissimus dorsi, serratus magnus, and pectoralis major, and had lost sensation along the outer surface of the arm and forearm, extending from the shoulder to the hand, and involving the thumb, including the thenar eminence and the posterior surface of the index finger and its metacarpal bone. In the other case a man aged forty was, last June, pitched off a cart on to his right shoulder and side of his head, and experienced violent pain. He lost power in the right upper limb in all the muscles except the small hand muscles and the flexors and extensors of the wrist, with anæsthesia along the outer surface of the limb, but less extensive than in the former case and not involving the index-finger. The lesion was considered to be in the cervical roots of the brachial plexus. The muscles affected, when compared with the lists of other authors, of the cervical roots were such as would be caused by a lesion of the fifth, sixth, and seventh cervical in the first case and of the fifth and sixth cervical in the second case, and these roots were considered to have been damaged. The prognosis was considered to be much better for lesions of the root than of the cord, so that treatment could be persevered with in the former, with a hope of recovery, even two years after the injury. The distribution of the muscles supplied by a root of the brachial plexus was considered to be of an anatomical and not a physiological nature.—The PRESIDENT remarked that if the centres for movements in the brain were grouped physiologically it was curious that in the cord and nerve roots the grouping should be anatomical.—Dr. BEEVOR replied that he admitted that the grouping in the spinal cord was physiological, but, in the light of the two cases narrated, he now believed that the arrangement in the nerve roots was an anatomical one.

CLINICAL SOCIETY OF LONDON.

Excision of Temporo-maxillary Articulation.—Rheumatoid Arthritis of Elbow-joints.—Meningocele.—Double Penis and Malformation of Genitals.—Charcot's Joint Disease.—Myositis Ossificans.—Deficient Tibiæ.—Ligature of Femoral Artery and Vein for Secondary Hæmorrhage.—Modified Incision for Removal of Vermiform Appendix.—Ligature of both External Iliac Arteries by Transperitoneal Method.—Premature Puberty.—Harelip and other Deformities.

AN ordinary meeting for the exhibition of clinical cases was held on Nov. 22nd, the President, Dr. BUZZARD, being in the chair.

Mr. ARBUTHNOT LANE showed photographs, taken before and after operation, of four children whose Temporo-maxillary Joints he had excised. The history of these cases had been previously related to the Society.

Mr. A. E. BARKER likewise showed a girl on whom he had performed Excision of the Temporo-maxillary Joint.

Dr. HARRY CAMPBELL showed a woman aged sixty-seven years who presented the lesions of Rheumatoid Arthritis limited to the Elbow-joints, though there was also grating in the wrists and temporo-maxillary joints. The affection began three years ago and was accompanied by much pain. The ends of the bones were much enlarged, and there was considerable swelling of the soft parts. He had aspirated the joints, but no fluid was discovered.

Dr. HINGSTON FOX showed a female infant aged twelve months who presented at the age of three months a small round Tumour in the centre of the Anterior Fontanelle, which the mother said had been noticed six weeks previously. The cranium was well formed, the circumference being 15⅝ in. There was no history of injury. The tumour had gradually increased in size, and measured 1¾ in. across and 1¼ in. in height. It did not pulsate and was irreducible. It did not vary with the respiratory movement. It was not tender or painful; in fact, the infant liked to have it handled. The cranium now measured 17½ in. The optic discs were normal. The child was intelligent, could walk a little, and had four teeth.

Mr. JOHN H. MORGAN showed an infant eighteen months old who presented the following Abnormalities of the External Genitals. On each side there was a large and well-formed mass of scrotal tissue containing well-formed testes, with spermatic cord and vas deferens. These were separated from each other at their upper extremity by two well-formed penes, which measured about three-quarters of an inch in length, the left being rather longer than the right. In each the frænum was absent, and the corona was but slightly marked. There was no urinary meatus in either. Each was attached to the ramus on either side, the pubic rami and symphysis being apparently normal. Below the root of these two organs was another prominent mass of tissue about three-quarters of an inch in length, consisting of a pouch of skin and subcutaneous tissue, in the centre of which was a firm and more fibrous body which was attached immediately below the two penes, lying midway between the two scrotal prominences, there being a deep sulcus on each side between it and these. Posteriorly to this finger-like process was a mass of skin and subcutaneous tissue covered by epithelium resembling that of skin except upon its posterior surface, where it was more like mucous membrane. This projected forward about half an inch and looked like a small mamma on which was a prominent bluish nipple. The left part of it was a small pedunculated body which stuck out like a small pea and was attached to the finger-like body. Below this, lying in the middle of the perineum and in front of the anus, was a prominent mass of mucous membrane measuring about one inch and a quarter from before backwards and three and three-quarter inches from

Digitized by Google

side to side. This was very red and vascular, and protruded when the child cried. Along its right attachment was a slit about half an inch long which admitted a probe into a long narrow cavity passing vertically upwards for about two inches, in which the probe could not be moved laterally. This was evidently the mucous membrane of the bladder, as the urine drained from this surface when the child was at rest, and when it cried was driven in jets from the orifices of the ureters, which could then be seen. Behind this protruding mucous membrane lay the anus, which easily admitted the little finger, but no abnormality could be detected in the rectum. The child presented no other abnormality except that at the upper part of the lobule of each ear there was a small fibrous prominence. Nothing abnormal could be discovered on auscultation of the heart, but the limbs became much cyanosed when it cried.

The PRESIDENT showed a woman aged thirty-eight years with symptoms of Tabes Dorsalis. Twenty months ago the right foot became severely swollen without pain. The mobility of the tarsal joint was interfered with, and the joint evidently contained fluid. Six months ago the whole of the *left* lower extremity became enormously swollen after an unusual amount of exercise, again without any pain. At present the left knee was greatly enlarged. There was great laxity of the ligaments of the joint, permitting lateral movement. The interest of the case lay in the fact that it was probably a very early stage of Charcot's disease, no destructive changes having as yet made their appearance. It belonged to the class described by Charcot as benign.—Dr. SANSOM asked whether the President had met with many cases of Charcot's disease accompanied by great pain, and thus simulating rheumatoid arthritis.—The PRESIDENT replied that he could call to mind a few cases with a certain amount of pain, but never to any great extent.

Mr. OWEN PAGET showed a child five years of age without first phalanges to the great toes, the metacarpal bones articulating directly with the second phalanges. The thumbs were apparently normal. The pectorales were ossified at their insertion, the latissimus dorsi was also ossified along its outer border, there was a similar condition of the sterno-mastoid muscle on both sides, and of a lymphatic channel in the left axilla. On the right side there was a node fixed to one of the ribs and another on the forehead. There was no history of any like disease in the family and no direct history of any rheumatic or gouty affection.

Mr. CLUTTON showed a boy aged fifteen years who had no right tibia, the fibula being the only bone in the leg. The foot, which had only three toes, articulated at right angles with the fibula. There was unusual development of the condyles of the femur, which were usually pointed in the absence of the tibia. The patella was well formed. Both hands were bifid, the middle fingers appeared to be absent, and the metacarpal bones on each side of the cleft were fused together. The boy was able to separate the digits to an abnormal degree. Mr. Clutton also passed round a photograph of similar deformity in a boy who likewise had extra fingers. The other patient he showed was a girl aged eight whose feet were at right angles with the fibulæ. The patellæ were small. One foot had four and the other five toes. She could get about with great facility either by a sort of amble or by short jumps.

Mr. C. S. WALLACE showed a man aged twenty-nine who had fallen a distance of twenty feet on to some railings, one of the spikes penetrating the inner side of the thigh, where it made an extensive lacerated and contused wound. It did not injure the femur, but it compressed the artery and vein. The wound was cleansed, but a day or two later it became septic, and on the fifth day the artery gave way and was ligatured above and below. Soon after the vein gave way also and was tied. The man had made a perfect recovery.—Mr. MAKINS remarked that the cause of the secondary hæmorrhage was the septic condition of the wound.—Mr. THOMAS SMITH said that formerly such a limb would have been amputated owing to the fear of gangrene supervening upon ligature of both artery and vein.

Mr. BATTLE showed a patient aged eighteen years on whom he had operated for Relapsing Appendicitis. He had modified the usual incision in order to prevent the subsequent formation of a hernia, which was so frequent a sequel of this operation. He made the incision one inch and a half to the inside of the linea semilunaris, and divided the anterior layer of the sheath of the rectus. The rectus muscle was then drawn to the inner side, and the posterior layer of the sheath and transversalis fascia exposed and divided, the inner incision not corresponding precisely to the external. The peritoneum was then divided. He was able to get at the appendix very well through this incision, and the result appeared to him to justify the slightly longer time it took. The layers were sutured from behind forwards, and as the rectus was allowed to return to its place it was thus interposed between the internal and external wounds in the abdominal wall. This procedure seemed, he thought, to hold out better hope of avoiding subsequent hernia.—Mr. CLUTTON thought it did not much matter where the incision was made, provided it did not pass exclusively through fibrous structures. He had not ordered a belt in these cases for two years and had seen no hernia result. Another method employed was to split each muscular layer in the line of its fibres.—Mr. BARKER said the procedure was not new; moreover, though he had operated on quite a number of these cases and had carefully looked out for the subsequent hernia, he had never seen one. The great thing was to make the opening as small and as short as possible, making it through muscle. It was desirable to get at the appendix wherever situated by the most direct route.—Mr. BATTLE, in reply, said he had seen several instances of the subsequent formation of hernia after the usual operation, though the patients themselves might not have been aware of the fact.
